### 1865 – Intercepting sewers complete

This map illustrates the extensive sewer intercepting system completed in 1865. The system is represented by a dense network of red lines that trace the course of the River Thames and its tributaries, including the Great Ouse, Lea, and Tyne. These lines connect various districts across London, from Willesden in the northwest to Bexley in the southeast. The River Thames itself is shown as a prominent blue line winding through the center of the city. Other geographical features include the River Great Ouse to the north and the River Lea to the east. The map also shows the locations of numerous districts and towns, such as Hampstead, Islington, Hackney, Stoke Newington, Leyton, Wanstead, Ilford, Dagenham, Barking, East Ham, West Ham, Stratford, Bow, Finsbury, Shoreditch, Camden Town, Marylebone, Paddington, Acton, Kensington, Chelsea, Lambeth, Bermondsey, Camberwell, Deptford, Greenwich, Woolwich, Bexley, Eltham, Catford, Lewisham, Brixton, Clapham, Wandsworth, Putney, Barnes, Chiswick, Hammersmith, and Merton. A scale bar in the bottom right corner indicates distances in kilometers (0, 1, 2, 3 km).

Overflow points along network prevents sewer flooding, but sewage is not treated

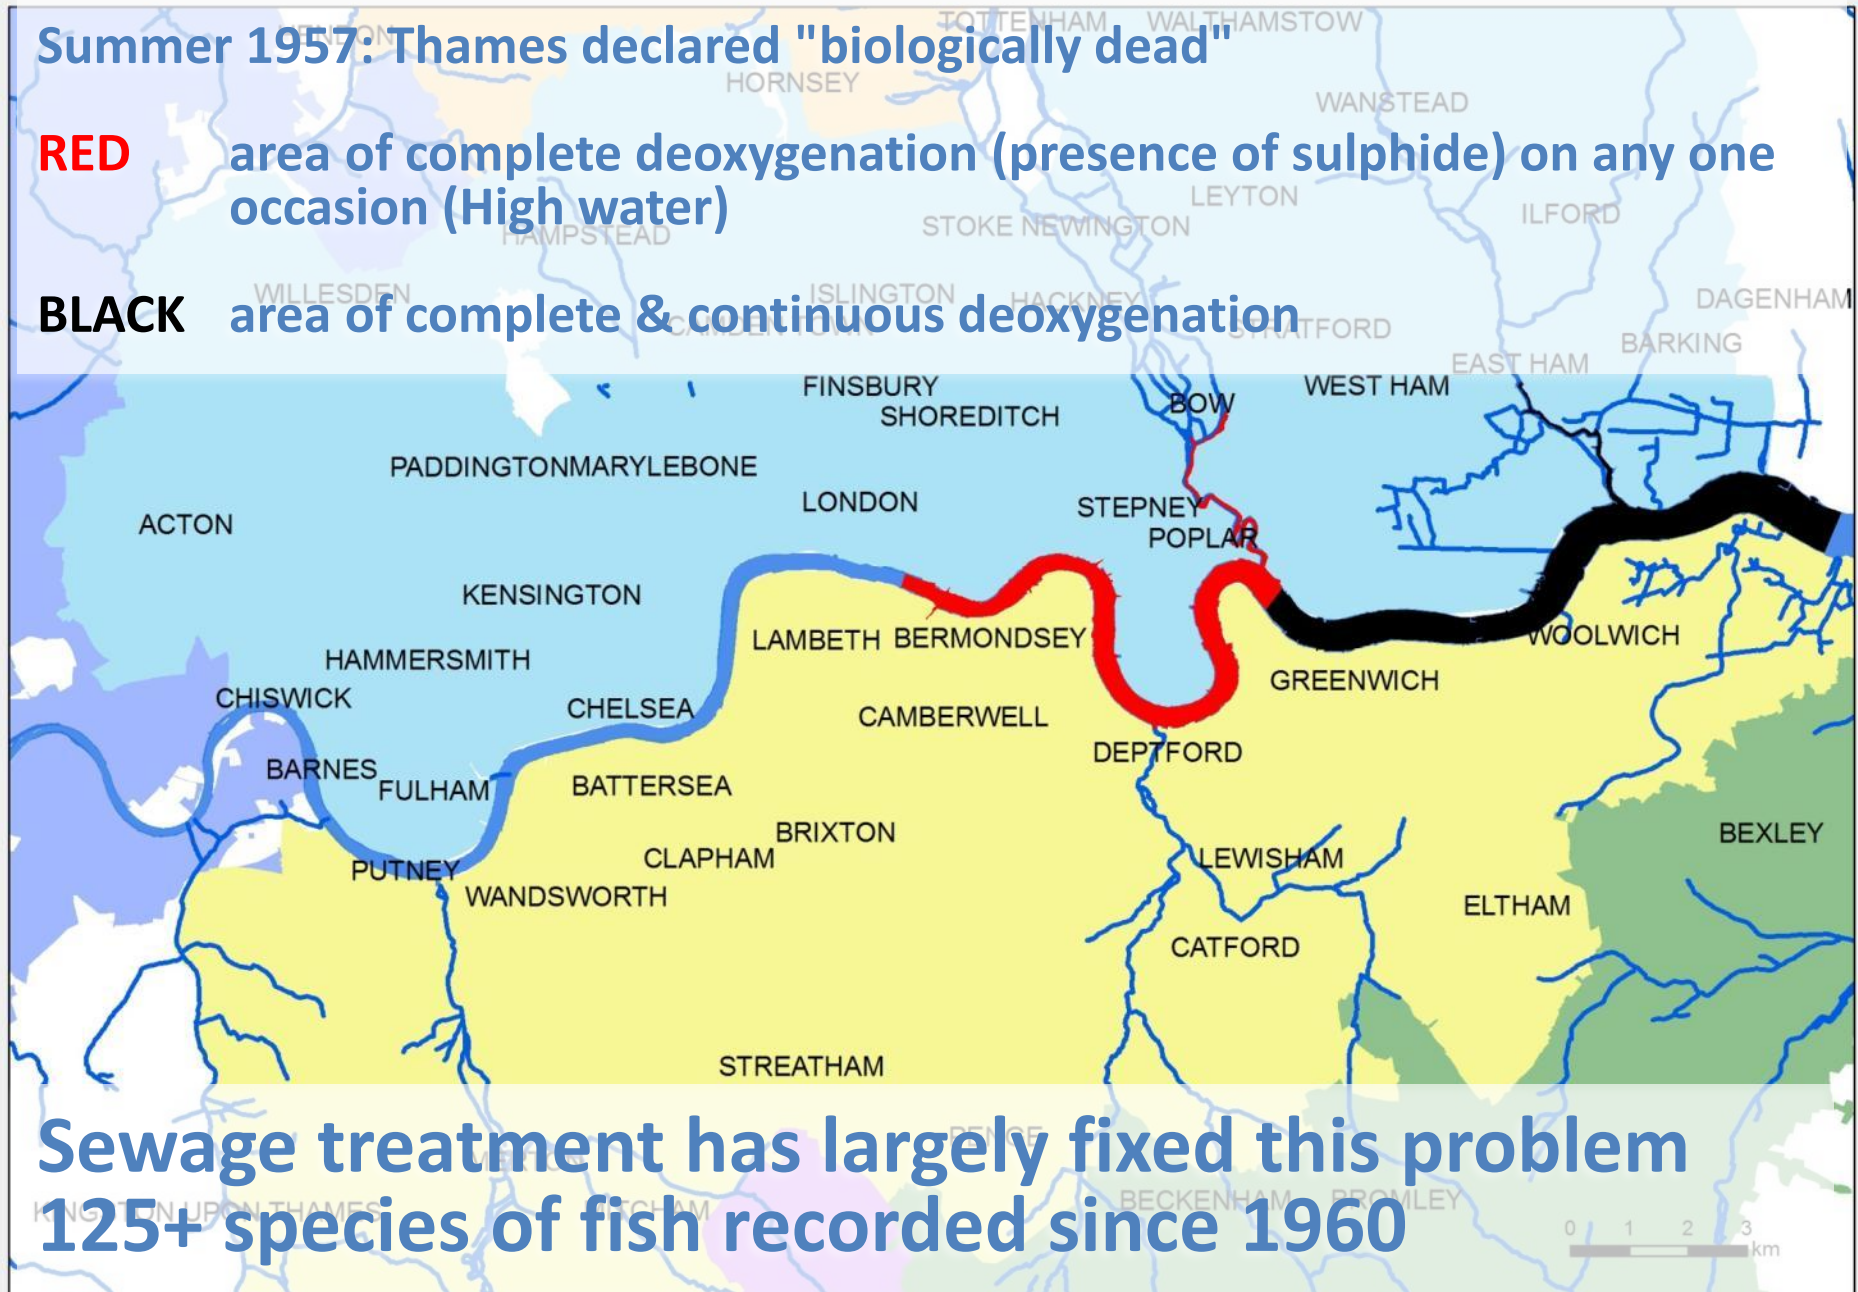

Summer 1957: Thames declared "biologically dead"

**RED** area of complete deoxygenation (presence of sulphide) on any one occasion (High water)

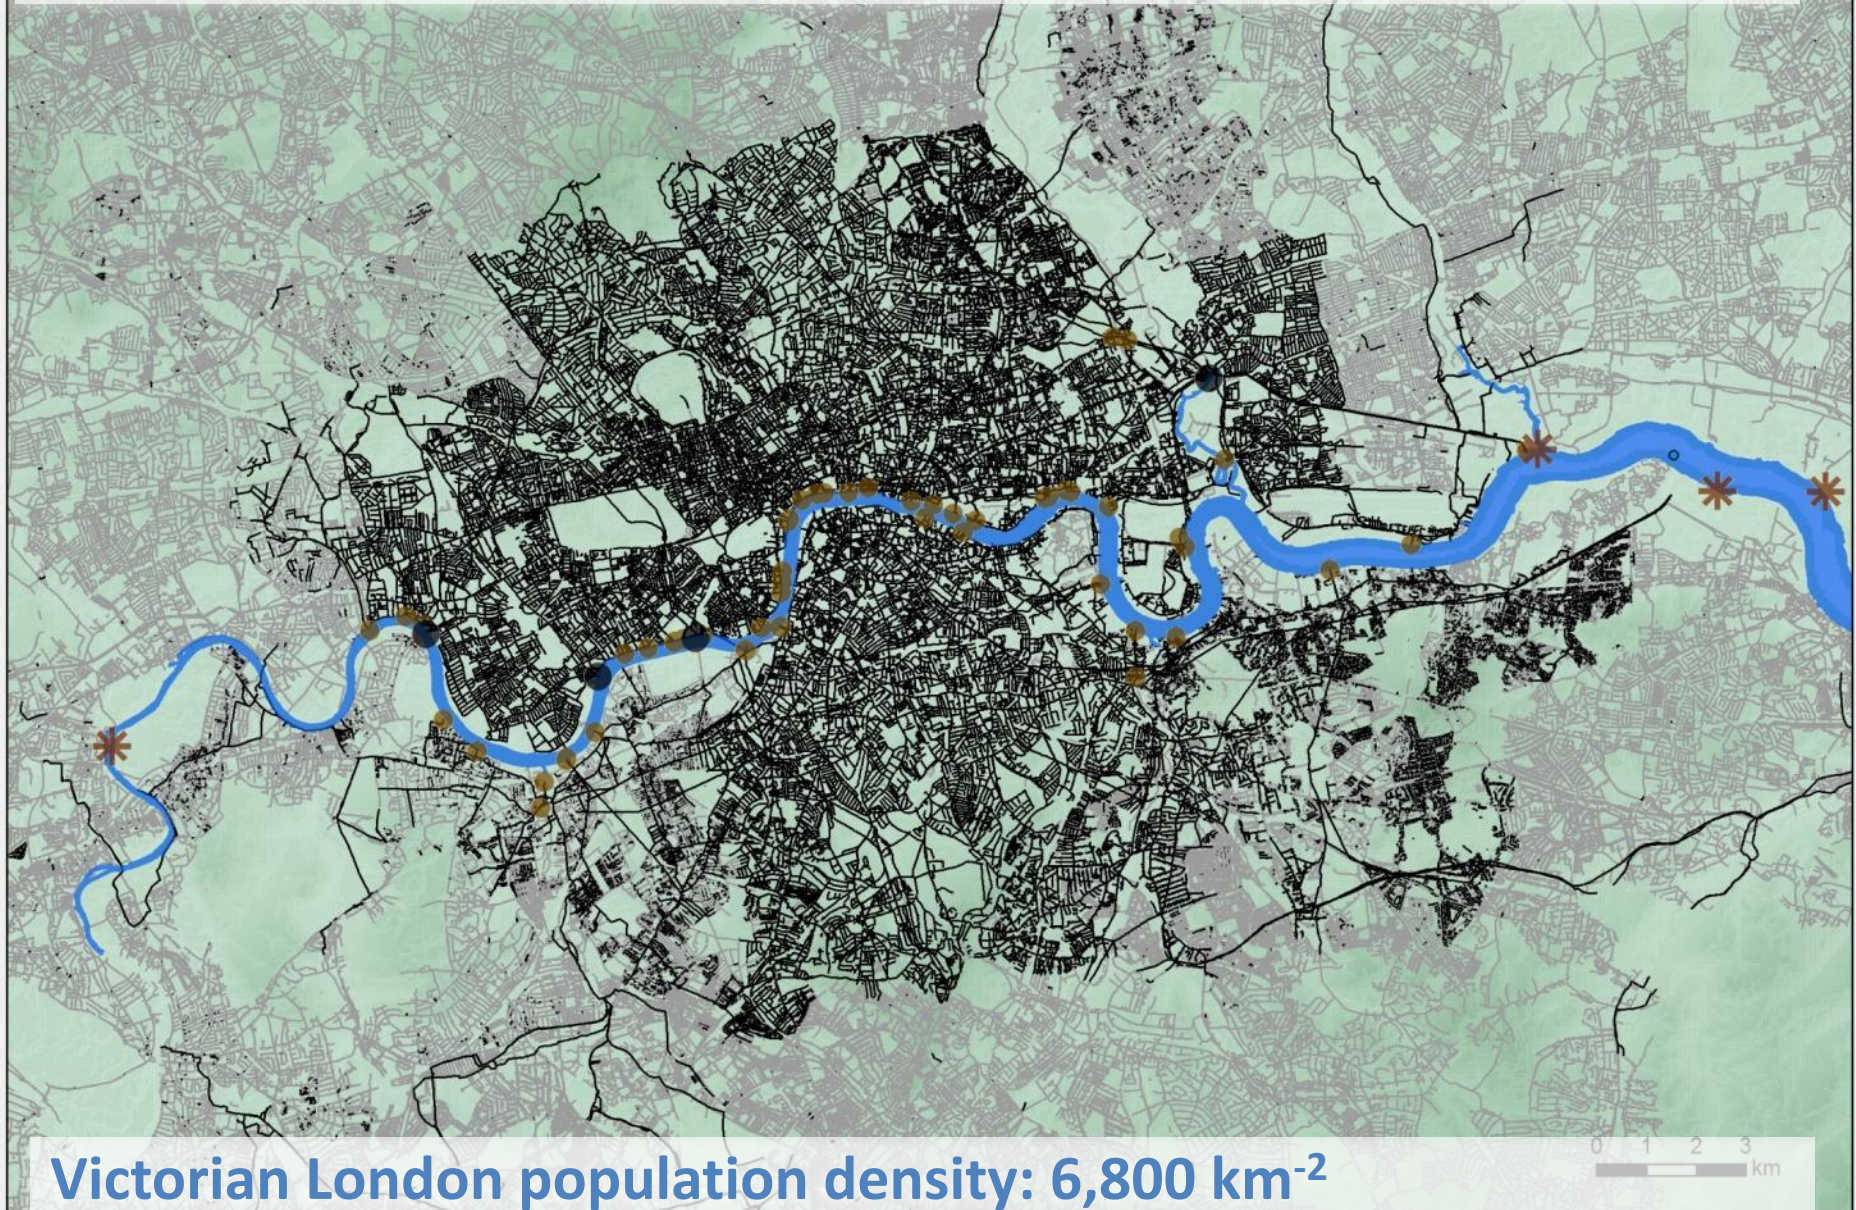

**BLACK** area of complete & continuous deoxygenation

Sewage treatment has largely fixed this problem  
125+ species of fish recorded since 1960

## Modern day collection system – combined drainage in black

Victorian London population density:  $6,800 \text{ km}^{-2}$   
Current population density:  $18,500 \text{ km}^{-2}$

0 1 2 3 km

55 million m<sup>3</sup> of untreated storm  
sewage discharged  
during ~60 spills in a typical year.

## Aesthetic impact

Elevated health risk

# Ecological damage

**Driver:**

# **Urban Waste Water Treatment Directive**

**Aim:** “protect the environment from the adverse effects of urban waste water”

**Overflows** (*intermittents*) should only discharge following unusually heavy rainfall. Measures should be taken to **limit pollution**

**Sewage works** - *must treat sufficiently under normal local climatic conditions*

*Sewerage system and pollution measures should be*  
**cost effective**

**Also Water Framework Directive measure**

# Thames Tideway Strategic Study (2000-2005)

## *TTSS Objective:*

*Reduce the impact of intermittent sewage discharges and further improve water quality in the Thames Tideway, to benefit the ecosystem, and facilitate use and enjoyment of the river.*

## *Members:*

*Thames Water, Environment Agency, Defra, Ofwat, with independent chair.*

- Define Objectives
- Investigate Solutions
- Make recommendations

# Dissolved Oxygen Design Objectives

Dissolved Oxygen (mg/l)	Return Period (years)	Duration (tides)	Basis
4	1	29	Protection against chronic effects (behavioural and physiological)
3	3	3	Managing scale and frequency of mortalities
2	5	1	
<b>1.5</b>	<b>10</b>	<b>1</b>	Protection against Mass mortalities <b>Return period better defined</b>
<i>Apply to any continuous length of river <math>\geq 3</math> km. Duration means that the DO must not fall below the limit for more than the stated number of tides. A tide is a single ebb or flood.</i>			

## **Solution Strategies considered:**

Before rainwater enters the system

Within the sewerage system

At the interface between the sewers and the river

In the river itself

# Strategy 1: **Prevent** rainwater entering the collection system

Retro-fitting of SuDS is disruptive and costly at best – technically infeasible at worst

No clear delivery mechanism

Even extremely optimistic scenarios fail to meet design objectives

No alternative means of disposal – watercourse or soakaway

## Strategy 2: **Make space within the sewerage system**

Problems in the London context:

In sewer detention increases flood risk

Additional on-line storage generally not possible

Off-line storage expensive and disruptive

Separation expensive and disruptive

## Strategy 3: **At the interface between the sewers and the river**

Several different ways to deal with intercepting the polluting flow at (or near) the CSOs evaluated

Only feasible concept was interception to a storage tunnel  
- this was recommended

Consistent with the approach taken to address historic urban catchment issues worldwide

## Strategy 4: **In-river treatment**

Does not meet requirement to “collect and treat”

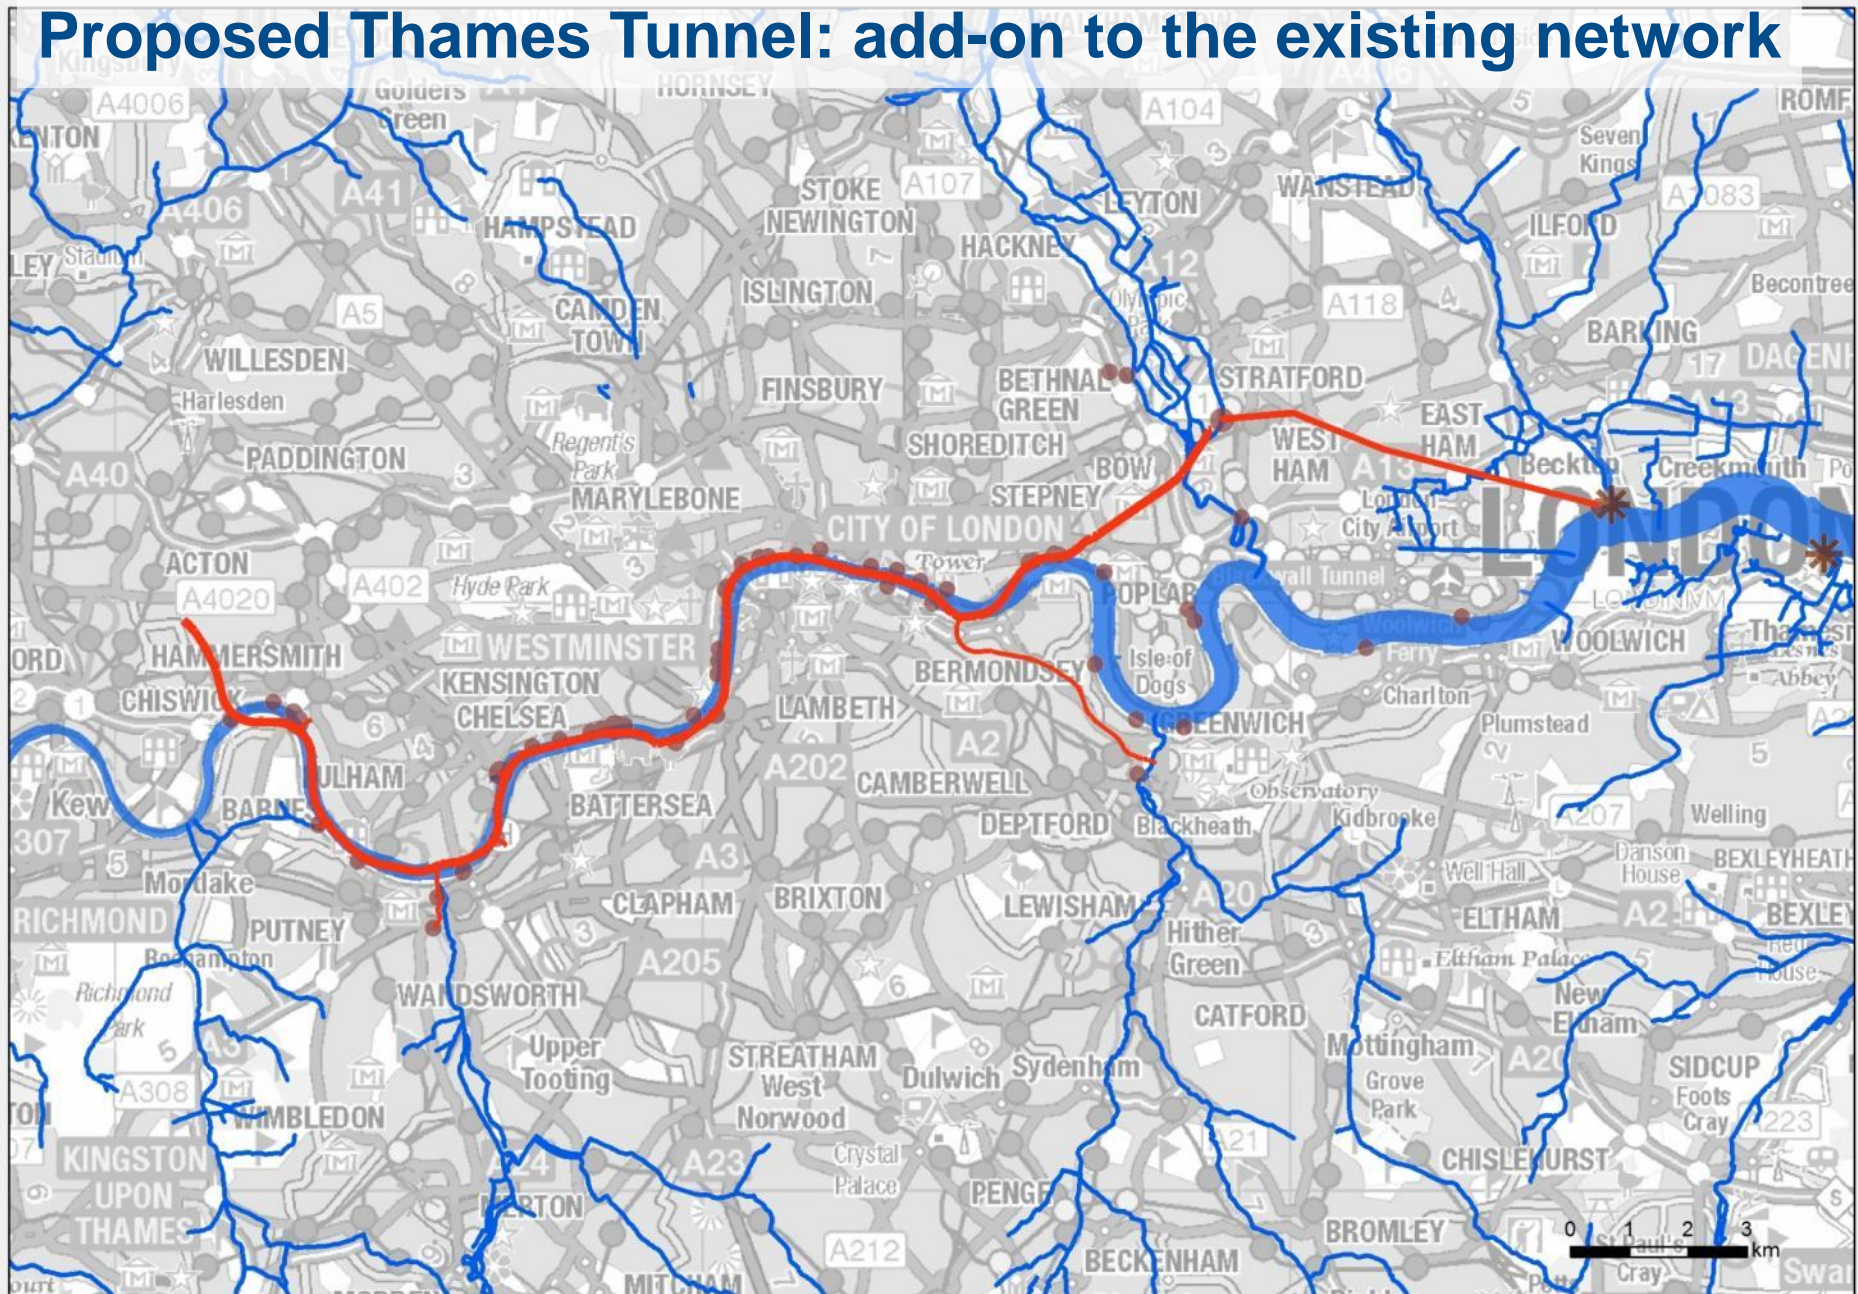

Oxygenation options only partially addresses dissolved oxygen issues

No existing technology remedies sewage litter or public health risk

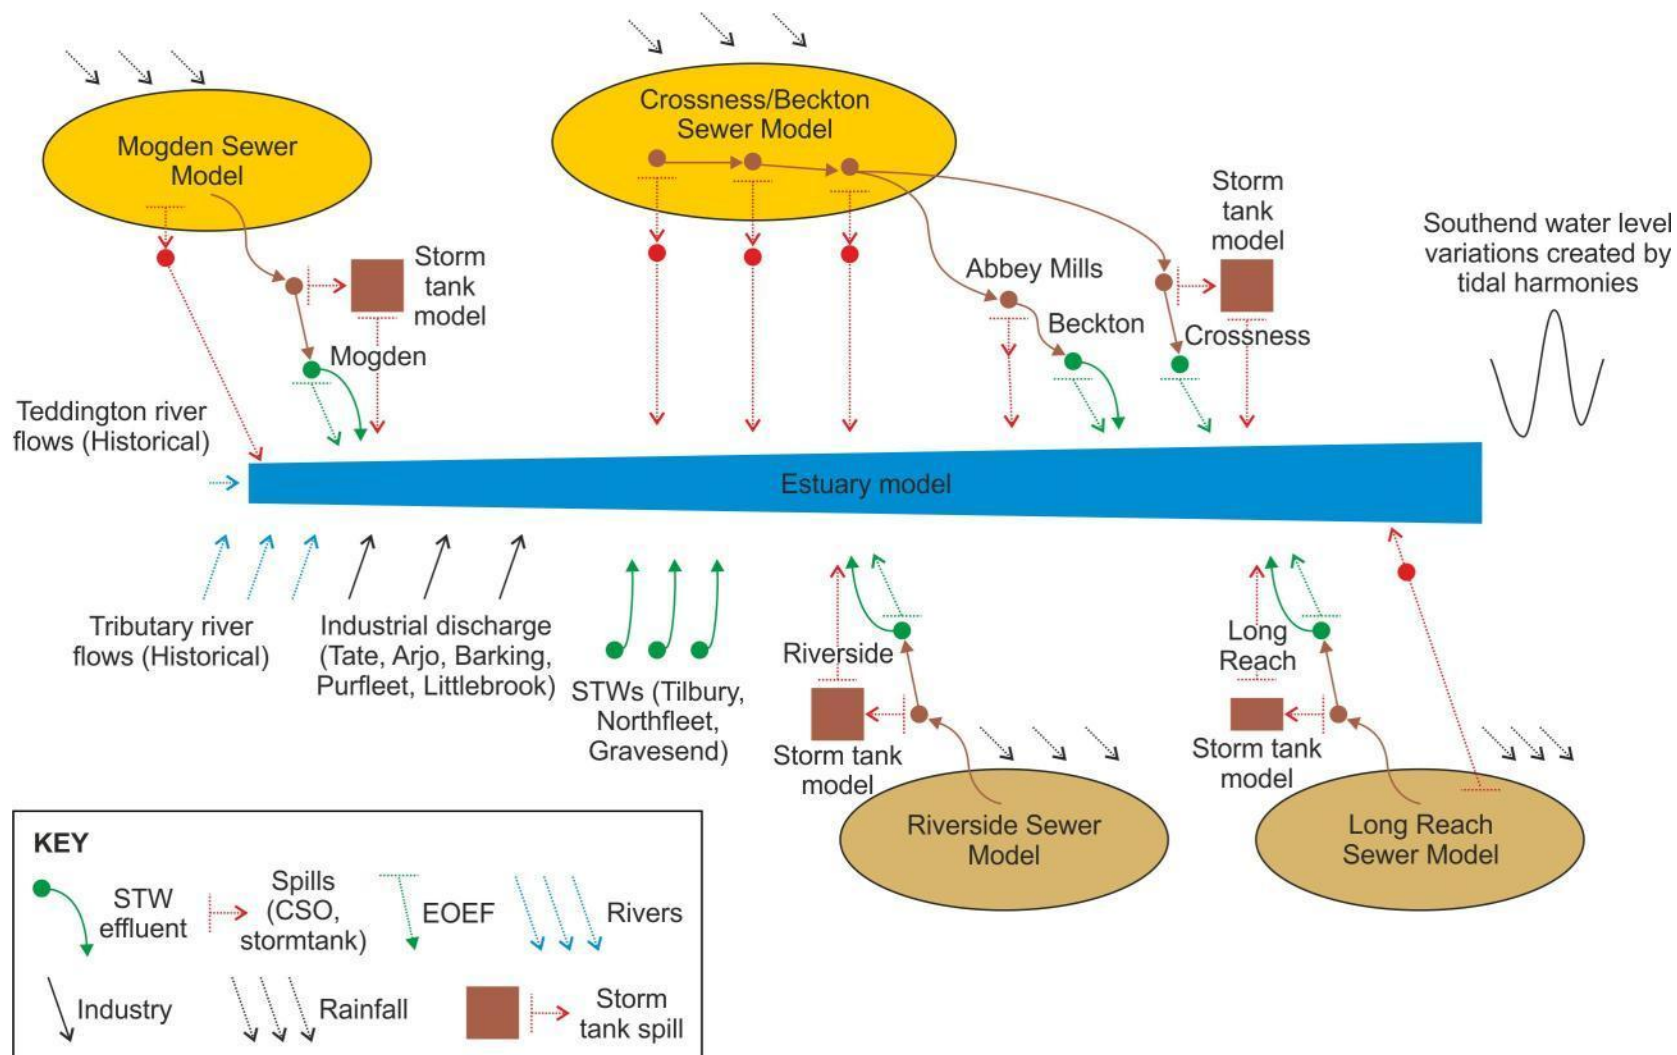

Navigation – impact on access and disruption to traffic unacceptable

# Proposed Thames Tunnel: add-on to the existing network

# How do we know the Thames Tideway Tunnels will work?

Thames Tideway Tunnel  
Construction: 2016-2023  
Length: 25 kilometres  
Diameter: 7.2 metres  
Capacity: 1.6 million m<sup>3</sup>  
Estimated cost: £4.2Bn (2011 prices)

# Thank you!
