

EC-Earth Global Climate Simulations - Ireland's Contributions to CMIP6

Authors: Paul Nolan and Alastair McKinstry

ENVIRONMENTAL PROTECTION AGENCY

The Environmental Protection Agency (EPA) is responsible for protecting and improving the environment as a valuable asset for the people of Ireland. We are committed to protecting people and the environment from the harmful effects of radiation and pollution.

The work of the EPA can be divided into three main areas:

Regulation: *We implement effective regulation and environmental compliance systems to deliver good environmental outcomes and target those who don't comply.*

Knowledge: *We provide high quality, targeted and timely environmental data, information and assessment to inform decision making at all levels.*

Advocacy: *We work with others to advocate for a clean, productive and well protected environment and for sustainable environmental behaviour.*

Our Responsibilities

Licensing

We regulate the following activities so that they do not endanger human health or harm the environment:

- waste facilities (*e.g. landfills, incinerators, waste transfer stations*);
- large scale industrial activities (*e.g. pharmaceutical, cement manufacturing, power plants*);
- intensive agriculture (*e.g. pigs, poultry*);
- the contained use and controlled release of Genetically Modified Organisms (*GMOs*);
- sources of ionising radiation (*e.g. x-ray and radiotherapy equipment, industrial sources*);
- large petrol storage facilities;
- waste water discharges;
- dumping at sea activities.

National Environmental Enforcement

- Conducting an annual programme of audits and inspections of EPA licensed facilities.
- Overseeing local authorities' environmental protection responsibilities.
- Supervising the supply of drinking water by public water suppliers.
- Working with local authorities and other agencies to tackle environmental crime by co-ordinating a national enforcement network, targeting offenders and overseeing remediation.
- Enforcing Regulations such as Waste Electrical and Electronic Equipment (WEEE), Restriction of Hazardous Substances (RoHS) and substances that deplete the ozone layer.
- Prosecuting those who flout environmental law and damage the environment.

Water Management

- Monitoring and reporting on the quality of rivers, lakes, transitional and coastal waters of Ireland and groundwaters; measuring water levels and river flows.
- National coordination and oversight of the Water Framework Directive.
- Monitoring and reporting on Bathing Water Quality.

Monitoring, Analysing and Reporting on the Environment

- Monitoring air quality and implementing the EU Clean Air for Europe (CAFÉ) Directive.
- Independent reporting to inform decision making by national and local government (*e.g. periodic reporting on the State of Ireland's Environment and Indicator Reports*).

Regulating Ireland's Greenhouse Gas Emissions

- Preparing Ireland's greenhouse gas inventories and projections.
- Implementing the Emissions Trading Directive, for over 100 of the largest producers of carbon dioxide in Ireland.

Environmental Research and Development

- Funding environmental research to identify pressures, inform policy and provide solutions in the areas of climate, water and sustainability.

Strategic Environmental Assessment

- Assessing the impact of proposed plans and programmes on the Irish environment (*e.g. major development plans*).

Radiological Protection

- Monitoring radiation levels, assessing exposure of people in Ireland to ionising radiation.
- Assisting in developing national plans for emergencies arising from nuclear accidents.
- Monitoring developments abroad relating to nuclear installations and radiological safety.
- Providing, or overseeing the provision of, specialist radiation protection services.

Guidance, Accessible Information and Education

- Providing advice and guidance to industry and the public on environmental and radiological protection topics.
- Providing timely and easily accessible environmental information to encourage public participation in environmental decision-making (*e.g. My Local Environment, Radon Maps*).
- Advising Government on matters relating to radiological safety and emergency response.
- Developing a National Hazardous Waste Management Plan to prevent and manage hazardous waste.

Awareness Raising and Behavioural Change

- Generating greater environmental awareness and influencing positive behavioural change by supporting businesses, communities and householders to become more resource efficient.
- Promoting radon testing in homes and workplaces and encouraging remediation where necessary.

Management and structure of the EPA

The EPA is managed by a full time Board, consisting of a Director General and five Directors. The work is carried out across five Offices:

- Office of Environmental Sustainability
- Office of Environmental Enforcement
- Office of Evidence and Assessment
- Office of Radiation Protection and Environmental Monitoring
- Office of Communications and Corporate Services

The EPA is assisted by an Advisory Committee of twelve members who meet regularly to discuss issues of concern and provide advice to the Board.

EPA RESEARCH PROGRAMME 2014–2020

EC-Earth Global Climate Simulations: Ireland's Contributions to CMIP6

(2015-CCRP-FS.23)

EPA Research Report

Prepared for the Environmental Protection Agency

ACKNOWLEDGEMENTS

This report is published as part of the EPA Research Programme 2014–2020. The EPA Research Programme is a Government of Ireland initiative funded by the Department of Communications, Climate Action and Environment. It is administered by the Environmental Protection Agency, which has the statutory function of co-ordinating and promoting environmental research.

The authors would like to acknowledge the members of the EPA project steering committee, namely Ray McGrath (University College Dublin), Philip O’Brien (EPA), Frank McGovern (EPA), Saji Varghese (Met Éireann), Anne Mason (EPA), Alice Wemaere (EPA), Keith Lambkin (Met Éireann), John O’Neill (Department of Communications, Climate Action and Environment), Patrick Fournet (Met Éireann) and Hazem Nagy (Marine Institute). In addition, the input of Jonathan McGovern, Met Éireann, is acknowledged.

The authors wish to acknowledge the Irish Centre for High-End Computing (ICHEC) for the provision of computational facilities and support. In particular, we are grateful to Eoin McHugh for his work on implementing the Earth System Grid Federation (ESGF) node at ICHEC and Marco Grossi and Niall Wilson, who assisted with the provision of ICHEC compute and storage resources. Finally, we wish to thank the European Centre for Medium-Range Weather Forecasts (ECMWF) (in particular, Paul Dando) for the provision of computational facilities and support.

DISCLAIMER

Although every effort has been made to ensure the accuracy of the material contained in this publication, complete accuracy cannot be guaranteed. The Environmental Protection Agency, the author and the steering committee members do not accept any responsibility whatsoever for loss or damage occasioned, or claimed to have been occasioned, in part or in full, as a consequence of any person acting, or refraining from acting, as a result of a matter contained in this publication. All or part of this publication may be reproduced without further permission, provided the source is acknowledged.

This report is based on research carried out/data from 2016 to 2019. More recent data may have become available since the research was completed.

The EPA Research Programme addresses the need for research in Ireland to inform policymakers and other stakeholders on a range of questions in relation to environmental protection. These reports are intended as contributions to the necessary debate on the protection of the environment.

Figure 2.50.	Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: global annual snowfall anomalies (%) with respect to the 30-year period, 1981–2010	68
Figure 2.51.	Annual mean SST (K), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	69
Figure 2.52.	EC-Earth annual mean SST bias (°C), 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1fl, (b) EC-Earth r9i1p1fl, (c) EC-Earth r11i1p1fl, (d) EC-Earth r13i1p1fl and (e) EC-Earth r15i1p1fl	70
Figure 2.53.	Mean SST for DJF (K), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	71
Figure 2.54.	EC-Earth mean SST bias (°C) for DJF, 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1fl, (b) EC-Earth r9i1p1fl, (c) EC-Earth r11i1p1fl, (d) EC-Earth r13i1p1fl and (e) EC-Earth r15i1p1fl	72
Figure 2.55.	Mean SST for JJA (K), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	73
Figure 2.56.	EC-Earth mean SST bias (°C) for JJA, 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1fl, (b) EC-Earth r9i1p1fl, (c) EC-Earth r11i1p1fl, (d) EC-Earth r13i1p1fl and (e) EC-Earth r15i1p1fl	74
Figure 2.57.	Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: (a) SST and (b) SST anomalies with respect to the 30-year period 1981–2010	75
Figure 2.58.	Northern Hemisphere annual mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	76
Figure 2.59.	Northern Hemisphere March mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	77
Figure 2.60.	Northern Hemisphere September mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1fl, (c) EC-Earth r9i1p1fl, (d) EC-Earth r11i1p1fl, (e) EC-Earth r13i1p1fl and (f) EC-Earth r15i1p1fl	78

Figure 2.61.	Southern Hemisphere annual mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1	79
Figure 2.62.	Southern Hemisphere March mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1	80
Figure 2.63.	Southern Hemisphere September mean sea ice fraction (%), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1	81
Figure 2.64.	Comparison of the EC-Earth Northern Hemisphere sea ice fraction (%) with ERA5 reanalysis data for the period 1979–2014: (a) annual, (b) March and (c) September	82
Figure 2.65.	Northern Hemisphere sea ice fraction anomalies with respect to the 30-year period 1981–2010: (a) annual, (b) March and (c) September	83
Figure 2.66.	Comparison of EC-Earth Southern Hemisphere sea ice fraction (%) with ERA5 reanalysis data for the period 1979–2014: (a) annual, (b) March and (c) September	84
Figure 2.67.	Southern Hemisphere sea ice fraction anomalies with respect to the 30-year period 1981–2010: (a) annual, (b) March and (c) September	85
Figure 3.1.	EC-Earth annual 2-m temperature projections (2041–2070 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	87
Figure 3.2.	EC-Earth annual 2-m temperature projections (2071–2100 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	87
Figure 3.3.	EC-Earth DJF 2-m temperature projections (2041–2070 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	88
Figure 3.4.	EC-Earth DJF 2-m temperature projections (2071–2100 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	88
Figure 3.5.	EC-Earth JJA 2-m temperature projections (2041–2070 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	89
Figure 3.6.	EC-Earth JJA 2-m temperature projections (2071–2100 vs 1981–2010, °C change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	89
Figure 3.7.	Global mean annual 2-m temperature anomalies with respect to the 30-year period 1981–2010: EC-Earth ensemble members r6i1p1f1, r9i1p1f1, r11i1p1f1, r13i1p1f1 and r15i1p1f1	90
Figure 3.8.	Standard deviation of the ensemble of annual 2-m temperature projections (2071–2100): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	91
Figure 3.9.	EC-Earth annual precipitation projections (2041–2070 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	91

Figure 3.10.	EC-Earth annual precipitation projections (2071–2100 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	92
Figure 3.11.	EC-Earth DJF precipitation projections (2041–2070 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	93
Figure 3.12.	EC-Earth DJF precipitation projections (2071–2100 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	93
Figure 3.13.	EC-Earth JJA precipitation projections (2041–2070 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	94
Figure 3.14.	EC-Earth JJA precipitation projections (2071–2100 vs 1981–2010, % change): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	94
Figure 3.15.	Global annual precipitation anomalies (%) with respect to the 30-year period 1981–2010: EC-Earth ensemble members r6i1p1fl, r9i1p1fl, r11i1p1fl, r13i1p1fl and r15i1p1fl	95
Figure 3.16.	Standard deviation of the ensemble of annual precipitation projections (2071–2100): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	95
Figure 3.17.	EC-Earth annual mean 10-m wind speed projections (2041–2070 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	96
Figure 3.18.	EC-Earth annual mean 10-m wind speed projections (2071–2100 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	97
Figure 3.19.	EC-Earth DJF mean 10-m wind speed projections (2041–2070 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	97
Figure 3.20.	EC-Earth DJF mean 10-m wind speed projections (2071–2100 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	98
Figure 3.21.	EC-Earth JJA mean 10-m wind speed projections (2041–2070 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	98
Figure 3.22.	EC-Earth JJA mean 10m wind speed projections (2071–2100 vs 1981–2010, m/s difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	99
Figure 3.23.	Global annual mean 10-m wind speed anomalies with respect to the 30-year period 1981–2010: EC-Earth ensemble members r6i1p1fl, r9i1p1fl, r11i1p1fl, r13i1p1fl and r15i1p1fl	99
Figure 3.24.	Standard deviation of the ensemble of annual mean 10-m wind speed projections (2071–2100): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	100

Figure 3.25.	EC-Earth annual MSLP projections (2041–2070 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	101
Figure 3.26.	EC-Earth annual MSLP projections (2071–2100 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	101
Figure 3.27.	EC-Earth DJF MSLP projections (2041–2070 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	102
Figure 3.28.	EC-Earth DJF MSLP projections (2071–2100 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	102
Figure 3.29.	EC-Earth JJA MSLP projections (2041–2070 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	103
Figure 3.30.	EC-Earth JJA MSLP projections (2071–2100 vs 1981–2010, hPa difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	103
Figure 3.31.	Global annual MSLP anomalies with respect to the 30-year period 1981–2010: EC-Earth ensemble members r6i1p1fl, r9i1p1fl, r11i1p1fl, r13i1p1fl and r15i1p1fl	104
Figure 3.32.	Standard deviation of the ensemble of Annual MSLP projections (2071–2100): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	104
Figure 3.33.	EC-Earth annual total cloud cover projections (2041–2070 vs 1981–2010, % difference); (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	105
Figure 3.34.	EC-Earth annual total cloud cover projections (2071–2100 vs 1981–2010, % difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	105
Figure 3.35.	EC-Earth DJF total cloud cover projections (2041–2070 vs 1981–2010, % difference): (a) SSP1–2.6, (b) SSP2–4.5, (c) SSP3–7.0 and (d) SSP5–8.5	106

Executive Summary

The global climate simulations described in this report constitute Ireland's contribution to the Coupled Model Intercomparison Project (CMIP) (phase 6) (CMIP6) and will be included for assessment in the United Nations Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report (AR6).

Since 1995, CMIP has co-ordinated climate model experiments involving multiple international modelling teams. The CMIP project has led to a better understanding of past, present and future climate, and CMIP model experiments have routinely been the basis for future climate change assessments carried out by the IPCC. The CMIP phase 5 (CMIP5) simulations have demonstrated the added value of improved models and enhanced resolution when compared with outputs from the CMIP phase 3 (CMIP3) project. This improvement in skill is expected to continue with the CMIP6 simulations.

The EC-Earth consortium participated in CMIP5 and is currently participating in CMIP6 using a model that includes biogeochemical cycles and atmospheric chemistry. The current version of EC-Earth is based on the European Centre for Medium-Range Weather Forecasts (ECMWF) Integrated Forecast System (IFS) atmospheric model, the Nucleus for European Modelling of the Ocean (NEMO) model, the Louvain-la-Neuve sea ice model (LIM3), the atmospheric Tracer Model version 5 (TM5), the Lund-Potsdam-Jena General Ecosystem Simulator (LPJ-GUESS) vegetation model and the Pelagic Interactions Scheme for Carbon and Ecosystem Studies (PISCES) ocean biogeochemistry model. Coupling is provided by OASIS3-MCT (the Ocean Atmosphere Sea Ice Soil – OASIS – coupler interfaced with the Model Coupling Toolkit – MCT).

As part of the current project, the EC-Earth Atmosphere–Ocean General Circulation Model (AOGCM) configuration was employed. The atmosphere was simulated with ~79-km horizontal grid spacings (T255) and 91 vertical levels. The ocean was simulated with 1-degree horizontal resolution and 75 vertical levels. In total, five historical (1850–2014) and 20 Scenario Model Intercomparison Project (ScenarioMIP) simulations (2015–2100) were run.

The future climate was simulated under the full range of ScenarioMIP “tier 1” shared socioeconomic pathways (SSPs); SSP1–2.6, SSP2–4.5, SSP3–7.0 and SSP5–8.5. For one ensemble member, all model levels were archived, allowing for regional downscaling using regional climate models and participation in the CMIP6 Coordinated Regional Downscaling Experiment (CORDEX) Model Intercomparison Project (MIP).

The EC-Earth CMIP6 simulations were run on the Irish Centre for High-End Computing (ICHEC) “kay” and ECMWF supercomputing systems. All CMIP6 data were published on the ICHEC Earth System Grid Federation (ESGF) node. The ESGF is an international effort of climate centres with a mission to support CMIP6 and future IPCC assessments. It is expected that the CMIP6 data, produced as part of the current report, will be analysed by the international research community during 2019/2020 for inclusion in the upcoming IPCC AR6.

Chapter 2 provides an overview of validations of 2-m temperature, precipitation, 10-m wind speed, mean sea level pressure (MSLP), total cloud cover, snowfall, sea surface temperature and sea ice fraction. The EC-Earth historical data were compared with Climatic Research Unit observational datasets and ERA5 global reanalysis data (ERA5 is the fifth generation of the ECMWF global climate reanalysis dataset). Results confirm the ability of the EC-Earth model to simulate the global climate with a high level of accuracy.

Chapter 3 provides an overview of EC-Earth global climate projections. The future global climate was simulated to the year 2100 under each of the four SSPs (SSP1–2.6, SSP2–4.5, SSP3–7.0 and SSP5–8.5). This results in 20 future global climate experiments (five ensembles multiplied by four SSPs). Projections of climate change were assessed by comparing the two 30-year future periods 2041–2070 and 2071–2100 with the 30-year historical period 1981–2010. Climate projections are presented for the Northern Hemisphere winter (December, January and February), Northern Hemisphere summer (June, July and August) and over the full year. Results show large projected increases in temperature; the largest are

noted over the land masses, in particular the northernmost regions and the Arctic. Projected temperature increases range from $\sim 0.5^{\circ}\text{C}$ over the Southern Hemisphere oceans for SSP1–2.6 (2041–2070) to $\sim 18^{\circ}\text{C}$ over the Arctic for SSP5–8.5 (2071–2100). By the year 2100, the global mean temperature is projected to increase by approximately 1.5°C , 2.8°C , 4.2°C and 5.5°C for SSP1–2.6, SSP2–4.5, SSP3–7.0 and SSP5–8.5, respectively. For precipitation, all ensemble members show a steady increase in mean global precipitation from around 2000, with a noticeable divergence between the SSPs around

2060. By the year 2100, global mean precipitation is projected to increase by approximately 4%, 6%, 8% and 10% for SSP1–2.6, SSP2–4.5, SSP3–7.0 and SSP5–8.5, respectively. Northern Hemisphere sea ice is projected to disappear in the September months by 2071–2100 under SSP2–4.5, SSP3–7.0 and SSP5–8.5. Projections of 10-m wind speed, MSLP, total cloud cover, snowfall and sea surface temperature are also presented in Chapter 3.

1 Introduction

Increasing greenhouse gas emissions and changing land use are having a significant effect on the Earth's climate. The Intergovernmental Panel on Climate Change (IPCC) has concluded that "warming of the climate system is unequivocal, and since the 1950s, many of the observed changes are unprecedented over decades to millennia" (IPCC, 2013a). It is *extremely likely* (95–100% probability) that human influence was the dominant cause of global warming between 1951 and 2010 (IPCC, 2013b) and was a contributor to global drought as early as 1900 (Marvel *et al.*, 2019). The United Nations has declared that the world experienced more unprecedented high-impact climate extremes in the first decade of the 21st century than in any previous decade (WMO, 2013). The IPCC estimates that there will be a rise in global mean surface temperatures of between 0.3 and 4.8°C by the late 21st century (IPCC, 2013a), with European mean temperatures projected to exceed the global mean. The authors project that the median temperature over Ireland for the period 2046–2065 will increase by 1–1.5°C in future summers and by 0.5–1.5°C in future winters under the representative concentration pathway (RCP) 4.5 scenario (IPCC, 2013c). In 2018, the IPCC published a special report "on the impacts of global warming of 1.5°C above pre-industrial levels and related global greenhouse gas emission pathways, in the context of strengthening the global response to the threat of climate change, sustainable development, and efforts to eradicate poverty" (IPCC, 2018). The report concluded that "human-induced warming reached approximately 1°C (likely between 0.8°C and 1.2°C) above pre-industrial levels in 2017, increasing at 0.2°C (likely between 0.1°C and 0.3°C) per decade (high confidence)". Furthermore, "warming greater than the global annual average is being experienced in many land regions and seasons, including two to three times higher in the Arctic". The authors concluded that global warming is likely to reach "1.5°C between 2030 and 2052 if it continues to increase at the current rate (high confidence)" and "temperature extremes on land are projected to warm more than the global mean surface temperature (high confidence): extreme hot days in mid-latitudes warm by up to about 3°C at global

warming of 1.5°C and about 4°C at 2°C, and extreme cold nights in high latitudes warm by up to about 4.5°C at 1.5°C and about 6°C at 2°C (high confidence)". The number of hot days is projected to "increase in most land regions, with highest increases in the tropics (high confidence)". The global water cycle is also projected to change significantly, with increases in disparity between wet and dry regions, as well as wet and dry seasons, with some regional exceptions (IPCC, 2013b). In 2018, the IPCC concluded that "risks from droughts and precipitation deficits are projected to be higher at 2°C compared to 1.5°C of global warming in some regions (medium confidence). Risks from heavy precipitation events are projected to be higher at 2°C compared to 1.5°C of global warming in several northern hemisphere high-latitude and/or high-elevation regions, eastern Asia and eastern North America (medium confidence)". In addition, "heavy precipitation associated with tropical cyclones is projected to be higher at 2°C compared to 1.5°C global warming (medium confidence)" (IPCC, 2018).

The IPCC (2013a) has concluded that "the rate of sea level rise since the mid-19th century has been larger than the mean rate during the previous two millennia (high confidence)" (IPCC, 2013a), and "over the period 1901 to 2010, global mean sea level (GMSL) rose by 0.19 (0.17 to 0.21)m" (Church *et al.*, 2013). Furthermore, results show that sea level rise is accelerating: "it is very likely that the mean rate of global averaged sea level rise was 1.7 (1.5 to 1.9)mm/yr between 1901 and 2010, 2.0 (1.7 to 2.3)mm/yr between 1971 and 2010, and 3.2 (2.8 to 3.6)mm/yr between 1993 and 2010" (Church *et al.*, 2013). These observed trends in global sea level rise (GSLR) were broadly confirmed by the *IPCC Special Report on the Ocean and Cryosphere in a Changing Climate* (IPCC, 2019; italics as in the original): "the total GMSL rise for 1902–2015 is 0.16 m (likely range 0.12–0.21 m)" and "the rate of GMSL rise for 2006–2015 of 3.6 mm yr⁻¹ (3.1–4.1 mm yr⁻¹, very likely range), is unprecedented over the last century (high confidence), and about 2.5 times the rate for 1901–1990 of 1.4 mm yr⁻¹ (0.8–2.0 mm yr⁻¹, very likely range)".

The IPCC (2019) also concluded that GSLR is projected to rise at an increasing rate and that “extreme sea level events that are historically rare (once per century in the recent past) are projected to occur frequently (at least once per year) at many locations by 2050 in all RCP scenarios, especially in tropical regions (high confidence)”. The GMSL rise “under RCP2.6 is projected to be 0.39m (0.26–0.53m, likely range) for the period 2081–2100, and 0.43m (0.29–0.59m, likely range) in 2100 with respect to 1986–2005. For RCP8.5, the corresponding GMSL rise is 0.71m (0.51–0.92m, likely range) for 2081–2100 and 0.84m (0.61–1.10m, likely range) in 2100” (IPCC, 2019). Furthermore, the average intensity of tropical cyclones, the proportion of category 4 and 5 tropical cyclones and the associated average precipitation rates are “projected to increase for a 2°C global temperature rise above any baseline period (*medium confidence*)” and “rising mean sea levels will contribute to higher extreme sea levels associated with tropical cyclones (*very high confidence*)” (italics as in the original).

Coastal areas are particularly vulnerable to the impacts of climate change. This is significant as coastal areas are home to a large proportion of the world's population; three-quarters of all large cities and 14 of the 17 largest cities lie on the coast and over 1.2 billion people globally live within 100km of the coast in areas where the land height is less than 100m above sea level (Small and Nichols, 2003). Rising sea levels, increased storminess and increases in extreme water levels will result in increased flooding, storm damage and erosion of coastal areas, which in turn pose risks to homes, buildings and other infrastructure, cause business and service interruptions, and have health and well-being effects. With regard to economic impact alone, a recent study by the European Union's Joint Research Centre (JRC) found that annual damages caused by coastal flooding in Europe, where one in three people live within 50km of the coast, will see a significant increase to between €93 billion and €961 billion by 2100 because of climate change (Vousdoukas *et al.*, 2018). The IPCC (2018) analysed the impact of global warming of a 1.5°C and found

that “projections of GMSL rise (relative to 1986–2005) suggest an indicative range of 0.26 to 0.77 m by 2100 for 1.5°C of global warming, 0.1 m (0.04–0.16 m) less than for a global warming of 2°C (medium confidence)”. The authors conclude that a “reduction of 0.1 m in GSLR implies that up to 10 million fewer people would be exposed to related risks, based on population in the year 2010 and assuming no adaptation (medium confidence)” (IPCC, 2018). The IPCC (2019) concluded that “coastal hazards will be exacerbated by an increase in the average intensity, magnitude of storm surge and precipitation rates of tropical cyclones”.

The analysis of a large ensemble of high-resolution regional climate simulations show that temperature projections for Ireland are in line with global projections, with an expected increase in annual 2-m temperatures over Ireland of 1.3°C (RCP4.5 scenario) and 1.6°C (RCP8.5 scenario) by mid-century, with the strongest signals noted in the east (Nolan, 2015; O'Sullivan *et al.*, 2015). Temperature increases are enhanced for the extremes; mid-century summer daytime and winter night-time temperatures are projected to increase by 0.7–2.6°C and 1.1–3.1°C, respectively (Nolan, 2015; O'Sullivan *et al.*, 2015). The number of frost and ice days is expected to decrease by approximately 50% by mid-century (Nolan, 2015). The rainfall climate is projected to become more variable, with an increase in extended dry periods during summer and an increase in the number of heavy rainfall events during autumn and winter (Nolan, 2015; Nolan *et al.*, 2017). By mid-century, significant decreases in the mean wind speed and energy content of the wind are projected for the spring, summer and autumn months. Projected increases for winter were found to be statistically insignificant (Nolan *et al.*, 2014; Nolan, 2015). Storms affecting Ireland are projected to decrease in frequency but increase in intensity, with increased risk of damage¹ (Nolan, 2015). The National Adaptation Framework (DCCA, 2018) estimated that the direct cost of flooding could rise from its current level of €192 million per annum to €1.15 billion if appropriate mitigation measures are not implemented.

¹ It should be noted that the projections of storm tracks exhibit medium to high uncertainty, as reflected in a large spread (disagreement) between ensemble members. In addition, as extreme storms are rare events, a large ensemble is required for a robust statistical analysis of the projections. Future work will focus on analysing a larger ensemble of downscaled CMIP6 data (including the EC-Earth data analysed in the current report).

1.1 The Coupled Model Intercomparison Project

Although the IPCC is regarded as the authoritative voice on climate change issues, it does not engage directly in climate research; its role is to assess the science based on the work of climate scientists through published peer-reviewed research. The Coupled Model Intercomparison Project (CMIP), an international group co-ordinating the running of simulations of the global climate system, has played a key role in supporting the IPCC in its previous assessment reports (e.g. Fifth Assessment Report – AR5) and is now fully engaged in its sixth phase (CMIP6) to support the IPCC with the next assessment report (Sixth Assessment Report – AR6), due to be released in 2021.

Since 1995, CMIP has co-ordinated climate model experiments involving multiple international modelling teams and provided a better understanding of past, present and future climate. The CMIP phase 5 (CMIP5) simulations have demonstrated the added value of enhanced resolution when compared with output from the CMIP phase 3 (CMIP3) project. There were significant improvements in the simulation of aspects of large-scale circulation, such as El Niño Southern Oscillation (ENSO) (Shaffrey *et al.*, 2009), tropical instability waves (Roberts *et al.*, 2009), the Gulf Stream and its influence on the atmosphere (Chassignet and Marshall, 2008; Kuwano-Yoshida *et al.*, 2010), the global water cycle (Demory *et al.*, 2014), extratropical cyclones and storm tracks (Hodges *et al.*, 2011) and Euro-Atlantic blocking (Jung *et al.*, 2012). In addition, the increased resolution enables more realistic simulation of small-scale phenomena with potentially severe impacts, such as tropical cyclones (Zhao *et al.*, 2009), tropical–extratropical interactions (Haarsma *et al.*, 2013) and polar lows. The improved simulation of climate also results in better representation of extreme events, such as heat waves, droughts and floods. Studies have shown that, even at 50-km grid spacing, global climate models (GCMs) severely under-resolve tropical cyclones, resulting in a substantial truncation of the intensity spectrum of simulated storms (Zhao *et al.*, 2009), and usually produce fewer events than the number observed (Camargo, 2013). The ability of CMIP5 models to simulate North Atlantic extratropical cyclones was assessed by Zappa *et al.* (2013). The

authors found that “systematic biases affect the number and intensity of North Atlantic cyclones in CMIP5 models. In December, January and February (DJF), the North Atlantic storm track tends to be either too zonal or displaced southward, thus leading to too few and weak cyclones over the Norwegian Sea and too many cyclones in central Europe. In June, July and August (JJA), the position of the North Atlantic storm track is generally well captured but some CMIP5 models underestimate the total number of cyclones”. Despite these biases, the representation of Northern Hemisphere storm tracks has improved from CMIP3 to CMIP5, with some CMIP5 models realistically representing both the number and the intensity of North Atlantic cyclones. In particular, some of the high-resolution atmospheric models tend to produce a better representation of the vertical tilt of the North Atlantic storm track and of the intensity of cyclones in DJF. This improvement in skill is expected to continue with the higher resolution CMIP6 simulations. This is particularly relevant for Ireland as improved skill in the simulation of CMIP6 storms will lead to sharper projections of North Atlantic storms, as simulated by regional climate models (RCMs), and a reduction in the uncertainty of these projections (see footnote 4). Sillmann *et al.* (2013) assessed the performance of CMIP5 GCMs in simulating climate extreme indices defined by the Expert Team on Climate Change Detection and Indices (ETCCDI), and compared it with that of the previous model generation (CMIP3). They found that, “for the precipitation indices, the intermodel uncertainty in the CMIP3 and CMIP5 ensembles is comparable, but the CMIP5 models tend to simulate more intense precipitation and fewer consecutive wet days than the CMIP3 models, and thus are closer to the observations”. This improvement is partly attributed to the generally higher spatial resolution of CMIP5 models than that of CMIP3 models (the effect of increasing resolution on precipitation extremes has been discussed, for instance, in Wehner *et al.*, 2010). Results indicate that, for the temperature indices, the performance of the CMIP3 and CMIP5 multi-model ensembles is similar with regard to their ensemble mean and median, but that the spread among CMIP3 models tends to be larger than among CMIP5 models, despite the larger number of models in the CMIP5 ensemble (Sillmann *et al.*, 2013). Again, this improvement in skill is expected to continue with the higher resolution CMIP6 simulations.

As part of the EC-Earth consortium, researchers at Met Éireann and the Irish Centre for High-End Computing (ICHEC) have implemented the EC-Earth model on various supercomputer platforms and have contributed to CMIP5 experiments, which formed an essential part of the IPCC AR5. The CMIP6 EC-Earth contributions (outlined in this report) will improve on the CMIP5 contributions and enhance the overall understanding of anthropogenic climate change on a global scale. The simulations will be included for assessment in the upcoming IPCC AR6 report.

1.1.1 The Coupled Model Intercomparison Project phase 6

The fundamental objective of CMIP is to improve the understanding of past, present and future climate change arising from natural variability or in response to changes in radiative forcing, principally linked to greenhouse gas emissions. The co-ordination feature of CMIP6 is very important as it enables the scientific community to focus more effectively on knowledge gaps in the understanding of the Earth's climate system, the themes of which are summarised under the Grand Science Challenges of the World Climate Research Programme (WCRP). In particular, CMIP6 will attempt to address the questions:

- How does the Earth system respond to forcing (e.g. from greenhouse gas emissions)?
- What are the origins and consequences of systematic climate model biases?
- How can we assess future climate changes given internal climate variability, predictability and uncertainties in emission scenarios?

More particularly, CMIP6 lays out a framework of climate simulations that supporting groups may choose to pursue. It includes the DECK (Diagnostic, Evaluation and Characterization of Klima) and historical simulations (1850 to near present), with the latter documenting the basic features of model performance across different phases of CMIP (Eyring *et al.*, 2015).

An agreed ensemble of Model Intercomparison Projects (MIPs), 21 in total, provides further refinement to address specific science topics. Of relevance to the current report is the Scenario Model Intercomparison Project (ScenarioMIP), which provides multi-model climate projections based on alternative scenarios of

future emissions and land use changes for at least the 21st century (Eyring *et al.*, 2015). Others include the Coordinated Regional Downscaling Experiment (CORDEX) diagnostic MIP, which focuses on regional climate, and the Decadal Climate Prediction Project (DCPP) MIP, which will investigate the ability to skilfully predict climate variations from a year to a decade ahead.

Irish participation in CMIP6 comes through the EC-Earth climate modelling consortium (see sections 1.3 and 1.5). EC-Earth participated in CMIP5 with EC-Earth v2.3 and in CMIP6 with a model that includes biogeochemical cycles and atmospheric chemistry (see section 1.2).

Crucially, CMIP6 requires that data outputs comply with common standards and are made publicly available, with supporting documentation, for analysis by the science community through the Earth System Grid Federation (ESGF) (see section 1.5).

1.2 EC-Earth Earth System Model

EC-Earth is an IPCC-class Earth system model (ESM) developed by a European consortium of which ICHEC and Met Éireann are members. CMIP6 (v3.3.1.1) is based on a newer cycle of the European Centre for Medium-Range Weather Forecast (ECMWF) Integrated Forecast System (IFS) atmospheric model (c36r4), the Nucleus for European Modelling of the Ocean (NEMO) model (v3.6), the Louvain-la-Neuve sea ice model (LIM3), the Tracer Model version 5 (TM5) atmospheric composition model, the Lund-Potsdam-Jena General Ecosystem Simulator (LPJ-GUESS) vegetation model and the Pelagic Interactions Scheme for Carbon and Ecosystem Studies (PISCES) ocean biogeochemistry model. Coupling is provided by OASIS3-MCT (the Ocean Atmosphere Sea Ice Soil – OASIS – coupler interfaced with the Model Coupling Toolkit – MCT) (see Figure 1.1). EC-Earth is optimised for a standard horizontal resolution of T255 with 91 vertical layers for the atmosphere, and for 1 degree with 75 layers for the ocean. In addition, high-resolution configurations are available: 0.25 degrees and 75 layers in the ocean, and T511 (~39 km) and T799 (~25 km) in the atmosphere.

The atmosphere component of the EC-Earth system is based on the IFS cy36r4 model, which has been used

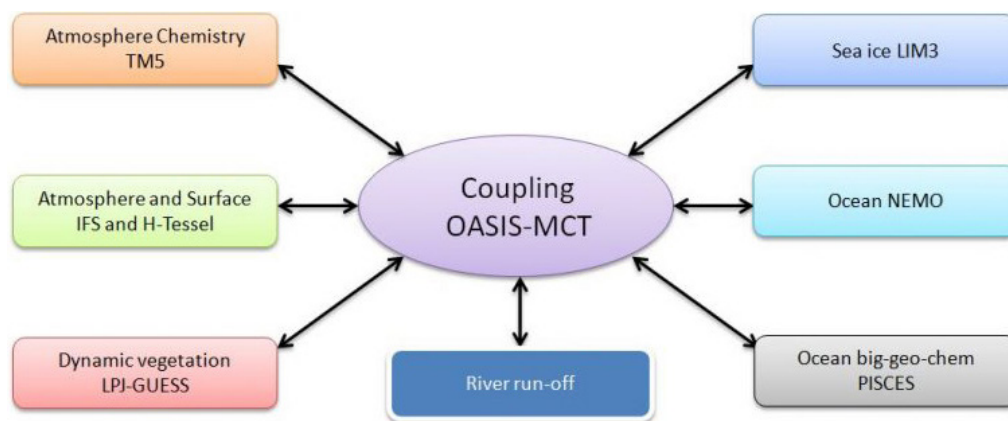

Figure 1.1. The CMIP6 EC-Earth model components.

operationally by the ECMWF for making seasonal predictions (Molteni *et al.*, 2011). The IFS is a spectral model of the atmosphere with a semi-Lagrangian advection scheme. A number of updates have been necessary to transform the IFS into a physical atmosphere model suitable as a GCM or ESM. The IFS is jointly developed and maintained by the ECMWF, based in Reading, England, and Météo-France, based in Toulouse. The Hydrology-Tiled ECMWF Scheme for Surface Exchanges over Land (H-TESEL) is used within the IFS for describing soil run-off and the evolution of soil, vegetation and snow over the continents at diverse spatial resolutions (Balsamo *et al.*, 2009).

The ocean component of the EC-Earth model is NEMO (Madec and the NEMO team, 2008). For CMIP6 version of EC-Earth, NEMO3.6 is used, which includes the ocean model OPA (Ocean PARallelise) and LIM3 (Rousset *et al.*, 2015). Ocean biogeochemical fluxes are represented with PISCES-v2 (Aumont *et al.*, 2015).

The atmospheric composition model of EC-Earth is TM5 (Huijnen *et al.*, 2010). It can be used for the interactive simulation of carbon dioxide (CO₂), methane (CH₄), ozone (O₃) and tropospheric aerosols.

The LPJ-GUESS dynamic vegetation and biogeochemistry model (Smith *et al.*, 2014) is the terrestrial biosphere component of EC-Earth,

simulating vegetation dynamics, land use and land management.

CMIP6 has a much increased set of model intercomparisons than previous generations. Figure 1.2 outlines the 21 CMIP6-approved MIPs. Of these, the EC-Earth community contributes to 18 using eight configurations of the EC-Earth model: EC-EARTH3 (the coupled Atmosphere–Ocean General Circulation Model – AOGCM; this configuration was used for the EC-Earth simulations in the current report), EC-EARTH3-HR (high resolution), EC-EARTH3-LR (low resolution), EC-EARTH3-CC (carbon cycle), EC-EARTH3-GrIS (Greenland ice sheet), EC-EARTH3-AerChem (air chemistry), EC-EARTH3-Veg (interactive vegetation) and EC-EARTH3-Veg-LR (low-resolution interactive vegetation).

1.3 The SSP/RCP Scenario Matrix Framework²

The CMIP6 ScenarioMIP utilises a parallel process of combining future socioeconomic pathways with forcing pathways to assess climate change (Moss *et al.*, 2010; Riahi *et al.*, 2017). This process includes the RCPs, which cover the climate forcing dimension of different possible futures (van Vuuren *et al.*, 2011), and served as the basis for the development of new climate change projections assessed in the IPCC AR5

² Text and figures in section 1.3 are taken from Riahi *et al.* (2017) and <https://www.carbonbrief.org/explainer-how-shared-socioeconomic-pathways-explore-future-climate-change> (accessed 11 February 2020). The article by Riahi *et al.* (2017) is an open access article distributed under the terms of the Creative Commons CC-BY license, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited. Material from <https://www.carbonbrief.org/explainer-how-shared-socioeconomic-pathways-explore-future-climate-change> can be reproduced unadapted under a Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 International Public License.

(Taylor *et al.*, 2012; IPCC, 2013b). The RCPs describe different levels of greenhouse gases and likely radiative forcings. Four pathways were developed, spanning a broad range of forcing in 2100 (2.6, 4.5, 6.0 and 8.5 W/m²), but purposefully did not include any socioeconomic “narratives” to go alongside them.

Other groups have focused on modelling how socioeconomic factors may change over the next century (Ebi *et al.*, 2014, Kriegler *et al.*, 2014, O’Neill *et al.*, 2014, van Vuuren *et al.*, 2014). These “shared socioeconomic pathways” (SSPs) look at five different ways in which the world might evolve in the absence of climate policy and how different levels of climate change mitigation could be achieved. The SSPs are based on five narratives describing alternative socioeconomic developments, including sustainable development, regional rivalry, inequality, fossil-fuelled development and middle-of-the-road development. The narrative for each of the five SSPs is described in Table 1.1.

The RCPs and SSPs were designed to be complementary. The RCPs set pathways for greenhouse gas concentrations and, effectively, the amount of warming that could occur by the end of the century, whereas the SSPs set the stage on which reductions in emissions will (or will not) be achieved. The new framework employed by the CMIP6

ScenarioMIP combines the SSPs and the RCPs in a scenario matrix architecture (see Figure 1.3).

1.4 Ireland’s Contributions to CMIP6

The EC-Earth simulations described in this report comprise Ireland’s contribution to CMIP6 and will be included for assessment in the United Nations IPCC AR6 report.

To date, CMIP6 participation is in the form of DECK CMIP contributions (historical) and ScenarioMIP contributions (Eyring *et al.*, 2015). Specifically, the following CMIP6 EC-Earth contributions were run:

- five T255L91-ORCA1L75 AOGCM CMIP6 historical simulations, 1850–2014;
- 20 ScenarioMIP simulations 2015–2100 – five T255L91-ORCA1L75 AOGCM CMIP6 simulations for each ScenarioMIP “tier 1” SSP-RCP (SSP1–2.6, SSP2–4.5, SSP3–7.0 and SSP5–8.5).

The EC-Earth AOGCM configuration was employed. The atmosphere was simulated with ~79-km horizontal grid spacings (T255) and 91 vertical levels. The ocean was simulated with 1-degree horizontal resolution and 75 vertical levels. In total, five historical and 20 “tier 1” ScenarioMIP simulations were run.

Table 1.1. Summary of SSP narratives

SSP	Narrative
SSP1	<p>“Sustainability – Taking the Green Road (Low challenges to mitigation and adaptation)</p> <p>The world shifts gradually, but pervasively, toward a more sustainable path, emphasising more inclusive development that respects perceived environmental boundaries. Management of the global commons slowly improves, educational and health investments accelerate the demographic transition, and the emphasis on economic growth shifts toward a broader emphasis on human well-being. Driven by an increasing commitment to achieving development goals, inequality is reduced both across and within countries. Consumption is oriented toward low material growth and lower resource and energy intensity.”</p>
SSP2	<p>“Middle of the Road (Medium challenges to mitigation and adaptation)</p> <p>The world follows a path in which social, economic, and technological trends do not shift markedly from historical patterns. Development and income growth proceeds unevenly, with some countries making relatively good progress while others fall short of expectations. Global and national institutions work toward but make slow progress in achieving sustainable development goals. Environmental systems experience degradation, although there are some improvements and overall the intensity of resource and energy use declines. Global population growth is moderate and levels off in the second half of the century. Income inequality persists or improves only slowly and challenges to reducing vulnerability to societal and environmental changes remain.”</p>
SSP3	<p>“Regional Rivalry – A Rocky Road (High challenges to mitigation and adaptation)</p> <p>A resurgent nationalism, concerns about competitiveness and security, and regional conflicts push countries to increasingly focus on domestic or, at most, regional issues. Policies shift over time to become increasingly oriented toward national and regional security issues. Countries focus on achieving energy and food security goals within their own regions at the expense of broader-based development. Investments in education and technological development decline. Economic development is slow, consumption is material-intensive, and inequalities persist or worsen over time. Population growth is low in industrialised and high in developing countries. A low international priority for addressing environmental concerns leads to strong environmental degradation in some regions.”</p>
SSP4	<p>“Inequality – A Road Divided (Low challenges to mitigation, high challenges to adaptation)</p> <p>Highly unequal investments in human capital, combined with increasing disparities in economic opportunity and political power, lead to increasing inequalities and stratification both across and within countries. Over time, a gap widens between an internationally-connected society that contributes to knowledge- and capital-intensive sectors of the global economy, and a fragmented collection of lower-income, poorly educated societies that work in a labor intensive, low-tech economy. Social cohesion degrades and conflict and unrest become increasingly common. Technology development is high in the high-tech economy and sectors. The globally connected energy sector diversifies, with investments in both carbon-intensive fuels like coal and unconventional oil, but also low-carbon energy sources. Environmental policies focus on local issues around middle and high income areas.”</p>
SSP5	<p>“Fossil-fueled Development – Taking the Highway (High challenges to mitigation, low challenges to adaptation)</p> <p>This world places increasing faith in competitive markets, innovation and participatory societies to produce rapid technological progress and development of human capital as the path to sustainable development. Global markets are increasingly integrated. There are also strong investments in health, education, and institutions to enhance human and social capital. At the same time, the push for economic and social development is coupled with the exploitation of abundant fossil fuel resources and the adoption of resource and energy intensive lifestyles around the world. All these factors lead to rapid growth of the global economy, while global population peaks and declines in the 21st century. Local environmental problems like air pollution are successfully managed. There is faith in the ability to effectively manage social and ecological systems, including by geo-engineering if necessary.”</p>

The ensemble members (historical and ScenarioMIP) are named r6i1p1f1, r9i1p1f1, r11i1p1f1, r13i1p1f1 and r15i1p1f1 (see section 1.4.1 for an overview of the ensemble naming convention). For ensemble member r11i1p1f1, all model levels are archived, allowing for regional downscaling using RCMs and participation in the CMIP6 CORDEX MIP. The choice of this particular ensemble member for downscaling was purely practical; sufficient storage resources for archiving of model-level data were available on the ICHEC systems when the r11i1p1f1 simulation commenced.

The raw EC-Earth datasets were post-processed (“cmorised”) and hosted on the ICHEC ESGF node (see section 1.5). In total, CMIP6 runs comprise over 2500 years of simulated data, over 500,000 files and 500TB of data (1 PB when including the backup of datasets on the ICHEC system). Table 1.2 provides an overview of variables archived at 3-hour and/or 6-hour temporal resolution. Additional variables, archived at daily and/or monthly temporal resolution, are listed in Box 1.1. Numerous fixed variables are also archived, such as land area fraction, surface altitude, sea floor depth and thickness of soil layers.

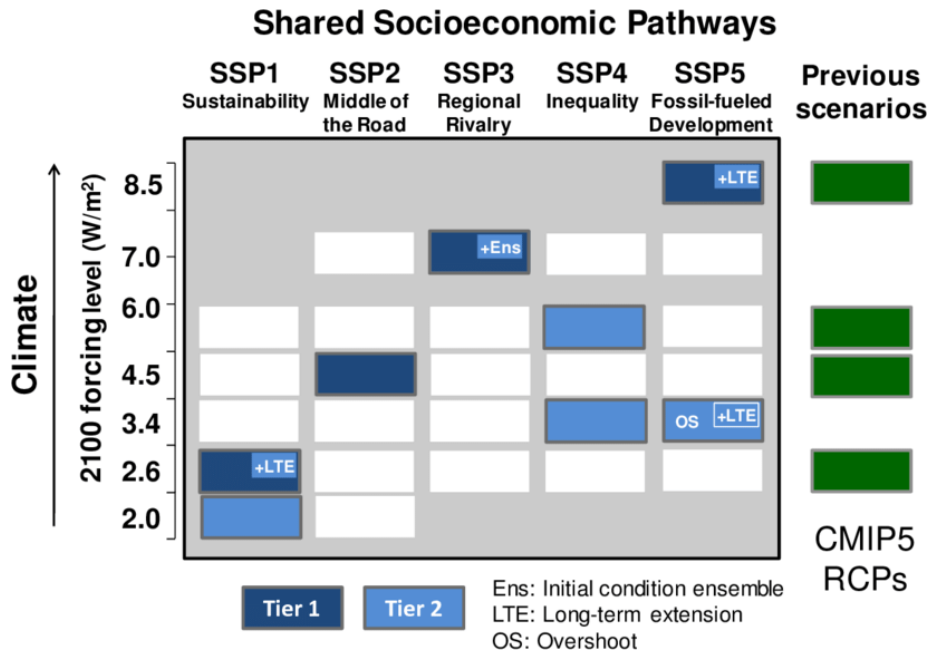

Figure 1.3. SSP-RCP scenario matrix illustrating ScenarioMIP simulations. Each cell in the matrix indicates a combination of a socioeconomic development pathway (i.e. an SSP) and a climate outcome based on a particular forcing pathway that current integrated assessment model runs have shown to be feasible (Riahi *et al.*, 2017). Dark blue cells indicate scenarios that will serve as the basis for climate model projections in tier 1 of ScenarioMIP; light blue cells indicate scenarios in Tier 2. Source: O’Neill *et al.* (2016). This work is distributed under the Creative Commons Attribution 3.0 License.

Current/future CMIP6 work will involve participation in the following MIPs: CORDEX regional downscaling, high-resolution (T511L91-ORCA025L75) HighResMIP and additional historical/ScenarioMIP simulations using the EC-Earth-Veg interactive vegetation configuration. Currently, the authors are running EC-Earth-Veg simulations comprising:

- two T255L91-ORCA1L75 EC-Earth-Veg historical simulations, 1850–2014;
- eight ScenarioMIP simulations, 2015–2100 – two T255L91-ORCA1L75 EC-Earth-Veg simulations for each ScenarioMIP “tier 1” SSP-RCP (SSP1–2.6, SSP2–4.5, SSP3–7.0 & SSP5–8.5).

These EC-Earth-Veg simulations are complete and will be hosted on the ICHEC ESGF node in March 2020.

1.4.1 CMIP6 ensemble member naming convention

For a given experiment, the *realisation_index*, *initialisation_index*, *physics_index* and *forcing_index* are used to uniquely identify each simulation of an ensemble of runs contributed by a single model.

These indices are defined as follows (Taylor *et al.*, 2018):

- *realisation_index* = an integer (≥ 1) distinguishing among members of an ensemble of simulations that differ only in their initial conditions (e.g. initialised from different points in a control run). Also, each so-called RCP (future scenario) simulation should normally be assigned the same realisation integer as the historical run from which it was initiated. This will allow users to easily splice together the appropriate historical and future runs.
- *initialisation_index* = an integer (≥ 1), which should be assigned a value of 1 except to distinguish simulations performed under the same conditions but with different initialisation procedures. In CMIP6 this index should invariably be assigned the value “1” except for some hindcast and forecast experiments called for by the DCP activity. The *initialisation_index* can be used either to distinguish between different algorithms used to impose initial conditions on a forecast or to distinguish between different observational datasets used to initialise a forecast.

Table 1.2. Description of EC-Earth variables hosted on the ICHEC ESGF node with at least 6-hour temporal resolution

Variable	Units	Description	Variable name	Time interval archived
Total cloud cover percentage	%	Total cloud area fraction (reported as a percentage) for the whole atmospheric column, as seen from the surface or the top of the atmosphere. Includes both large-scale and convective cloud	clt	3 hours, day, month
Surface upward latent heat flux	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Upward" indicates a vector component, which is positive when directed upward (negative downward). The surface latent heat flux is the exchange of heat between the surface and the air on account of evaporation (including sublimation)	hfls	3 hour, day, month
Surface upward sensible heat flux	W/m ²	The surface sensible heat flux, also called turbulent heat flux, is the exchange of heat between the surface and the air by motion of air	hfss	3 hour, day, month
Near-surface specific humidity	1	Near-surface (usually 2-m) specific humidity	huss	3 hours, day, month
Total run-off	kg/m ² /s	The total run-off (including drainage through the base of the soil model) per unit area leaving the land portion of the grid cell	mrro	3 hours, day, month
Moisture in upper portion of soil column	kg/m ²	The mass of water in all phases in the upper 10 cm of the soil layer	mrsos	3 hours, day, month
Precipitation	kg/m ² /s	Precipitation; includes both liquid and solid phases	pr	3 hours, day, month
Convective precipitation	kg/m ² /s	Convective precipitation at the surface; includes both liquid and solid phases	prc	3 hours, day, month
Snowfall flux	Kg/m ² /s	At the surface; includes precipitation of all forms of water in the solid phase; 3-hour mean snowfall flux	prsn	3 hours, day, month
Surface air pressure	Pa	Surface pressure; two-dimensional field to calculate the three-dimensional pressure field from hybrid co-ordinates	ps	3 hours, 6 hours, day, month
Surface downwelling longwave radiation	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Longwave" means longwave radiation. Downwelling radiation is radiation from above; it does not mean "net downward"	rlds	3 hours, day, month
Surface downwelling clear-sky longwave radiation	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Longwave" means longwave radiation. Downwelling radiation is radiation from above; it does not mean "net downward"	rldscs	3 hours, month
Surface upwelling longwave radiation	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Longwave" means longwave radiation. Upwelling radiation is radiation from below; it does not mean "net upward"	rlus	3 hours, day, month
Surface downwelling shortwave radiation	W/m ²	Surface solar irradiance for ultraviolet radiation calculations	rsds	3 hours, day, month
Surface downwelling clear-sky shortwave radiation	W/m ²	Surface solar clear-sky irradiance for ultraviolet radiation calculations	rsdscs	3 hours, month
Surface upwelling shortwave radiation	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Shortwave" means shortwave radiation. Upwelling radiation is radiation from below; it does not mean "net upward"	rsus	3 hours, day, month
Surface upwelling clear-sky shortwave radiation	W/m ²	The surface called "surface" means the lower boundary of the atmosphere. "Shortwave" means shortwave radiation. Upwelling radiation is radiation from below; it does not mean "net upward"	rsuscs	3 hours, month
Near-surface air temperature	K	Near-surface (usually 2 m) air temperature	tas	3 hours, day, month
Surface temperature where land or sea ice	K	Surface temperature of all surfaces except the open ocean	tslsi	3 hours, day

Table 1.2. Continued

Variable	Units	Description	Variable name	Time interval archived
Eastward component of the 10-m wind	m/s	Sampled synoptically	uas	3 hours, day, month
Northward component of the 10-m wind	m/s	Sampled synoptically	vas	3 hours, day, month
Sea surface temperature	°C	Temperature of the upper boundary of the liquid ocean, including temperatures below the sea ice and floating ice shelves	tos	3 hours, day, month
Surface temperature	K	Surface/skin temperature	ts	3 hours, month
Near-surface relative humidity	%	The relative humidity with respect to liquid water for T>0°C, and with respect to ice for T<0°C	hurs	6 hours, day, month
Relative vorticity at 850 hPa	/s	The upward component of the vorticity vector	rv850	6 hours
Eastward wind at 100 m	m/s	Zonal wind at 100-m height	ua100m	6 hours
Northward wind at 100 m	m/s	Meridional wind at 100-m height	va100m	6 hours
Maximum 10-m wind speed of gust	m/s	Wind speed gust maximum at 10 m above the surface	wsgmax10m	6 hours
Sea level pressure	Pa	Sea level pressure	psl	6 hours, day, month
Air temperature	K	Air temperature on pressure levels	ta	6 hours, day, month
Eastward wind	m/s	Zonal wind (positive in a eastward direction) on pressure levels	ua	6 hours, day, month
Northward wind	m/s	Meridional wind (positive in a northward direction) on pressure levels	va	6 hours, day, month
Geopotential height	m	The geopotential divided by the standard acceleration due to gravity (on pressure tropospheric levels)	zg	6 hours, day, month
Geopotential height at 500 hPa	m	Geopotential height on the 500-hPa surface	zg500	6 hours, day
Temperature of soil	K	Temperature of the soil. Reported as missing for grid cells with no land	tsl	6 hours, month

Box 1.1. List of EC-Earth variables hosted on the ICHEC ESGF node with daily and monthly temporal resolutions

Daily variables (52 in total)

clt, hfls, hfss, hur, hurs, hursmax, hursmin, hus, huss, mrro, mrso, mrsos, omldamax, pr, prc, prsn, psl, rlds, rlus, rlut, rsds, rsus, sfcWind, sfcWindmax, siconc, siconca, sisnthick, sispeed, sitemptop, sithick, sitimefrac, siu, siv, snc, snw, ta, ta850, tas, tasmax, tasmin, tauu, tauv, tos, tossq, tslsi, ua, uas, va, vas, wap, zg and zg500

Monthly variables (147 in total)

bigtheta, bigthetaoga, clivi, clt, clwvi, evs, evspsbl, ficeberg, friver, fsitherm, hfbasin, hfbasinpadv, hfds, hfdsn, hfevapds, hfgeou, hflbthermids, hfls, hfrainds, hfss, hfx, hfy, htovgyre, htovovrt, hur, hurs, hus, huss, lwsl, masscello, masso, mlotst, mlotstmax, mlotstmin, mlotstsq, mrfo, mrro, ros, mrso, mrsol, mrsos, msftbarot, ps, psl, pso, rlds, rldscs, rls, rlus, rlut, rlutcs, rsdo, rsds, rsdscs, rsdt, rsntds, rss, rsus, rsuscs, rsut, rsutcs, rtmt, sbl, sfcWind, sfcWindmax, sfdsi, siage, sicompstren, siconc, siconca, sidivvel, sidmassevapsubl, sidmassgrowthbot, sidmassgrowthwat, sidmassmeltbot, sidmassmelttop, sidmasssi, sidmasstranx, sidmasstrany, siflswdtop, sihc, simass, sisali, sisnmass, sisnthick, sispeed, sitemptop, sithick, sitimefrac, siu, siv, sivol, sltovgyre, sltovovrt, snc, snd, sndmassmelt, sndmasssnf, snm, snw, so, sob, sog, sos, sosga, t20d, ta, tas, tasmax, tasmin, tauu, tauuo, tauv, tauvo, thetao, thetaoga, thetaot, thetaot2000, thetaot300, thetaot700, thkcello, tob, tos, tosga, tossq, ts, tsl, tsn, ua, uas, umo, uo, va, vas, vmo, vo, volo, wap, wfo, wfonocorr, wmo, wo, zg, zhalf, zos, zossq and zostoga

For a full description of the variables see <https://earthsystemcog.org/projects/wip/CMIP6DataRequest> (accessed 11 February 2020).

- `physics_index` = an integer (≥ 1) identifying the physics version used by the model. In the usual case of a single physics version of a model, this argument should normally be assigned the value 1, but it is essential that a consistent assignment of `physics_index` be used across all simulations performed by a particular model. Use of “`physics_index`” is reserved for closely-related model versions (e.g., as in a “perturbed physics” ensemble) or for the same model run with slightly different parameterisations (e.g., of cloud physics). Model versions that are substantially different from one another should be given a different “`source_id`” (rather than simply assigning a different value of the `physics_index`).
- `forcing_index` = an integer (≥ 1) used to distinguish runs conforming to the protocol of a single CMIP6 experiment, but with different variants of forcing applied. One can, for example, distinguish between two historical simulations, one forced with the CMIP6-recommended forcing data sets and another forced by a different dataset, which might yield information about how forcing uncertainty affects the simulation.

For example, the `r6i1p1f1` simulation of the current research is the sixth EC-Earth consortium ensemble member (`r6`) and uses standard initialisation procedures (`i1`) and standard EC-Earth physics (`p1`) and CMIP6-recommended forcings (`f1`). The choice of ensemble members of the current project (i.e. `r6`, `r9`, `r11`, `r13` and `r15`) has no specific research significance; initial ensemble members were assigned to the consortium members by alphabetical order of institute.

1.4.2 Implementation of EC-Earth on ICHEC and ECMWF supercomputing systems

The EC-Earth CMIP6 simulations were run on both ICHEC “`kay`” and ECMWF supercomputing systems. EC-Earth passed the “reproducibility experiments” and demonstrated that the system is stable and that the results are robust, regardless of high-performance computing (HPC) platform used. These experiments involved running hundreds of years of simulation of both IFS-only and AOGCM configurations on (1) ECMWF `cca` with intel compilers, (2) ECMWF `cca` with cray compilers and (3) ICHEC `kay` with intel compilers.

The results of the reproducibility tests demonstrated the following:

- Using the cray compilers on the ECMWF system is significantly more computationally efficient. However, the cray reproducibility tests did not pass and therefore the EC-Earth consortium was advised to use the intel compilers in place of cray compilers on the ECMWF system. The EC-Earth reproducibility protocol was designed by the EC-Earth community (Massonnet *et al.*, 2019) to assess the reproducibility of the EC-Earth model system. This protocol is based on a statistical comparison of standard climate metrics derived from multi-ensembles of multi-decadal control integrations executed in different HPC environments.
- The ICHEC `kay` machine (using intel compilers) passed the reproducibility tests and the runs were found to be computationally efficient. The results informed the decision to run the majority of the CMIP6 runs on the ICHEC machine.
- The ELPiN (Exclude Land Processes in NEMO) software greatly improved the efficiency of EC-Earth.

EC-Earth was found to run relatively slowly on the ECMWF system and so a careful scale testing was completed to determine the optimal configuration. Table 1.3 presents scaling statistics for the EC-Earth AOGCM on the ECMWF `cca` machine using intel compilers. The simulated time was 1 month. Three “forking” strategies were considered: no forking (not shown), all nodes shared (ShareAll) and dedicated nodes for IFS with other components sharing nodes (not shown). `rmf_numproc` (river run-off module) was set to 1 in all cases and the ELPiN land removal tool was implemented. The configuration highlighted in blue was found to be optimal and was implemented for the CMIP6 production runs. Table 1.4 presents similar scaling results for the ICHEC `kay` machine and demonstrates that EC-Earth runs approximately twice as fast at ICHEC compared with the ECMWF.

1.5 ESGF: The Earth System Grid Federation

The ESGF (Cinquini *et al.*, 2014) is a peer-to-peer collaborative system that develops, deploys and maintains software infrastructure for the management,

Table 1.3. Scaling results for a 1-month EC-Earth simulation on ECMWF/cca using the intel compilers^a

^aThe configuration highlighted in blue (repeated for confirmation of results) was found to be the most efficient and was used for the CMIP6 EC-Earth production runs. The system billing unit (SBU) is used for accounting of computing resources on the ECMWF machines; the SYPD metric is the number of simulated years per day; and CHPSY is a measure of the core hours per simulated year.

dissemination and analysis of model output and observational data (Observations for Model Intercomparison Project or Obs4MIPS; Ferraro *et al.*, 2015). It is an international effort of climate centres with a mission to support CMIP6 and future assessments, support the dissemination of data and improve the automated processing of the data. Model simulations, satellite observations and reanalysis products are all being served from the ESGF Peer-to-Peer (P2P) distributed data archive.

ESGF P2P is a component architecture expressly designed to handle large-scale data management for worldwide distribution. The architecture was developed by a team of computer and climate scientists as an operational system for serving climate data from multiple locations and sources.

An ESGF node consists of a web front-end, allowing users to search for data, along with a data node and, optionally, an identity provider, an index and compute components. In current releases (available at <https://github.com/ESGF>), the ESGF front-end has been rewritten to use CoG, a collaborative environment allowing the hosting of multiple projects, providing links not just to the data but also to project files and various

wiki resources. It now also interoperates directly with ES-DOC (n.d.), to provide automated documentation for ESMs using the Common Information Model (CIM).

1.5.1 Implementation of the ICHEC ESGF node

At ICHEC, we use esgf.ichec.ie to host the CMIP6 datasets. In addition, the ICHEC ESGF node hosts the national CMIP5 EC-Earth contributions, along with EC-Earth output from the PMP3 experiment at the Royal Netherlands Meteorological Institute (KNMI), CORDEX downscaling from Maynooth University (Fealy *et al.*, 2018) and “HiResIreland” high-resolution (~4 km) regional downscaled CMIP5 projections data from ICHEC/Environmental Protection Agency (Nolan, 2015).

ICHEC rebuilt the ESGF node in 2019 on a virtual machine running CentOS 7.6; the virtual machine host is directly connected to the storage system, providing 10 Gbit/s throughput to the underlying storage hardware. The underlying storage system (iRODS, <https://www.irods.org/>) was reinstalled, with iRODS software upgraded to client 4.1.11. We use the iRODS

Table 1.4. Scaling results for a 1-month EC-Earth simulation on the ICHEC system using the intel compilers^a

^aThe configuration highlighted in blue was found to be the most efficient and was used for the CMIP6 EC-Earth production runs. The SYPD (simulated days per day) is the number of EC-Earth-simulated years that complete in 24 hours.

FUSE (Filesystem in Userspace) mount to provide a filesystem view of the iRODS storage as /esg/data on the virtual machine node. We also moved to the Docker version of ESGF (ESGF_DOCKER, n.d.). The ESGF Docker project aims to provide Docker containers for each of the components of the ESGF software stack, as an alternative to the traditional installer. This means that the search component (esgf-solr) runs in a different container from the database component (esgf-postgres) or publisher component (esgf-publisher); serious or security bugs in one will not affect the other containers, and components can be rebuilt and launched independently. At the time of decision, this looked likely to become the default production version; however, since then, most existing nodes have opted to continue with the traditional install version, making ICHEC's node the only operational Dockerised implementation at this time (see Figure 1.4). Although some bugfixes were required, the Dockerised version has been stable at ICHEC and so we have proceeded to use it for production.

The ESGF node at ICHEC is now automatically deployed from ICHEC's continuous integration system, allowing new instances to be built from scratch in minutes. This has allowed for test instances

(esgf-test.ichec.ie) to be trivially built to test out new configuration changes, and ESGF system stability has been greatly improved. Containerisation has also meant that multiple instances of the publisher component can be run in parallel, which is crucial as the publisher contains a data scan step that is time-consuming. Furthermore, the file system can be mounted differently in each Docker component, allowing for different IO (input/output) strategies to be deployed. This was useful as different configurations are optimal for the different components; the main THREDDS component, publishing files to the outside world, benefits from large block sizes and consumes multiple file handles. THREDDS, by default, keeps multiple files open, presuming that there are multiple readers, each downloading the whole file. Alternatively, the publish/scan step is tuned for small block sizes as the publisher reads a single file at a time, but does many small reads and seeks as it validates the metadata within a NetCDF file. As of January 2020, we are seeing sustained download rates of over 1 Gbit/s from the ICHEC ESGF node; 10 Gbit/s should be possible on the underlying hardware.

ICHEC runs an identity provider container, allowing users to create logins on the node. However, we recommend that users login from the main ESGF

Figure 1.4. Docker-based architecture for a complete ICHEC ESGF node. Orange boxes are components hosted in virtual machines within ICHEC; purple containers are internal databases. See <https://cedadev.github.io/esgf-docker/> (accessed 11 February 2020) for further details.

nodes. The ESGF architecture also includes server-side compute components but these are not currently enabled at ICHEC.

1.5.2 Publishing to the ESGF

All of the “cmorised” simulation output from EC-Earth is in the form of NetCDF files. Each experiment produces ~250 datasets, each consisting of between 80 and 160 files. Each dataset is a single variable for a given simulation for various temporal resolutions (e.g. 3 hours, 6 hours, daily, monthly). In total, the CMIP6 work at ICHEC currently amounts to over 10,000 files shared on the ESGF.

CMIP specifies in detail how data are organised and published (Eyring *et al.*, 2015). The NetCDF files have standardised metadata (such as processing history, tracking IDs, institutions) and variables defined with standardised units and specified in agreed controlled vocabularies. Although weather and climate data are typically published to standards using the “CF” (climate and forecasting) convention, CMIP goes beyond this to define agreed time-averaging and grid specification recommendations. These are then enforced with the software CMOR (Climate Model Output Rewriter) version 3 (CMOR3; <https://github.com/PCMDI/cmor>).

Compared with CMIP5, CMIP6 has tighter standards for data organisation: files on the server are better organised (agreed directory structures; better naming conventions for models within consortiums, such as EC-Earth; conventions on storing versioned sets of model outputs to enable better retraction and updates where necessary). The EC-Earth community standardised on “EC-Earth-Consortium” as `institution_id`. In comparison, for CMIP5, ICHEC was registered as an institution.

Each data node manager is then registered with ES-DOC (n.d.) with publishing rights. EC-Earth uses multiple data nodes (ICHEC, the National Supercomputer Centre at Linköping University in Sweden, KNMI in the Netherlands, the Barcelona Supercomputing Center and the Danish Meteorological Institute). Once the data are present on the data nodes, the metadata are sent to the search indexes. ICHEC currently uses the DKRZ (German Climate Computing Centre) as the index node. DKRZ then forwards this indexing information to the rest of the ESGF.

Publication consists of the following steps:

- Data are converted from EC-Earth output formats (GRIB and NetCDF for different atmosphere and ocean components) using *ece2cmor*. This post-processing took approximately 1 hour for 1 year of data using 20 parallel cores.
- A new Pre-Publication Attribute Reviewer for ESGF (PrePARE) is used to check attributes.
- Data are uploaded to the ESGF node, with agreed directory structures. These are set in *esg.ini* in the ESGF configuration for each model. Each file contains one variable for a given experiment, with filenames specified and checked in *esg.ini*.
- Mapfiles are generated for each dataset using *esgmapfile*. This checks file structures (including directories, names and attributes) and checksums.
- A python library, CDF2CIM, is used to extract metadata from the NetCDF files during the map generation phase. A CIM2 (JSON format) file documenting the metadata is then uploaded to ES-DOC on the publication of datasets to the ESGF.
- Datasets are published on the ESGF node with *esgpublish*. The datasets are recorded in the node dataset and THREDDs database and are available locally for checking.
- The metadata are then pushed to the index node (using *esgpublish --publish*) to make the files visible beyond the data node.

Data availability can be limited by local policies to allow visibility to certain users only or enforced groups of users, for example the “CMIP_Research” group can have greater access to files during validation. Such group membership is enforced by the identity provider, which provides the OpenID logins that are authenticated within the ESGF using SAML (Security Assertion Markup Language) authentication. Hence, we recommend that users register for an OpenID at the main sites (e.g. DKRZ) so that they have the appropriate group memberships.

The CMIP and ESGF projects have a defined process in place for updates if required; every file has a *tracking_id* and every dataset has a version number. In the event of errors and corrections, the existing dataset is retracted (unpublished) on the ESGF node and a replacement with a new version number published; by convention, in CMIP6 a date-type version number is used (e.g. “20190710” is currently

used). On the ESGF node, it is possible to search and view both current and previous versions in the index.

The tracking_id in each file is a unique hash of the file, allowing a backwards search on the portals to be carried out to discover where a given file came from (although the filename can also be used for this, the filename may be changed over time as it is copied from place to place). The tracking_id can also be used to discover if the file has been retracted or replaced.

1.5.3 Further ESGF work

As of August 2019, all EC-Earth AOGCM CMIP6 datasets, produced as part of the current report, are published on the ICHEC ESGF node. It is expected that the CMIP6 data will be analysed by the international research community over the coming

months for inclusion in the upcoming IPCC AR6 report. From previous experience, downloads will continue until data from a follow-on CMIP7 become available over the next decade. ICHEC will continue to publish the data until then, including additional CMIP6 contributions and follow-on downscaling work, and will work on integrating CMIP6 outputs into other projects, such as the Climate Ireland portal (www.climateireland.ie).

1.5.4 ESGF acknowledgements

We gratefully acknowledge Eoin McHugh at ICHEC for working through iRODS and ESGF installation bugs, making possible the reproducible installation of the ESGF at ICHEC, and Katharina Berger at DKRZ and Prashanth Dwarakanath at Linköping University for testing and resolving multiple ESGF issues.

2 EC-Earth Validations

The EC-Earth ensemble members were validated by comparing the historical datasets with Climatic Research Unit (CRU) observational datasets and ERA5 global reanalysis data (ERA5 is the fifth generation of the ECMWF global climate reanalysis dataset; C3S, 2017). As outlined in Chapter 1, the historical climate was simulated using the EC-Earth T255L91-ORCA1L75 AOGCM configuration. The atmosphere was simulated with ~79-km horizontal grid spacings (T255) and 91 vertical levels. The ocean was simulated with 1-degree horizontal resolution and 75 vertical levels. In total, the historical climate was simulated using five ensemble members (r6i1p1f1, r9i1p1f1, r11i1p1f1, r13i1p1f1 and r15i1p1f1) for the period 1850–2014.

2.1 Observational and Reanalysis Datasets

2.1.1 ERA5 global reanalysis

Reanalysis provides a numerical description of the recent climate by combining models with observations. ERA5 is currently available for the period 1979 to within 3 months of real time. Subsequent releases of ERA5 will cover the earlier decades from 1950 and will be available to within 7 days of real time. ERA5 was produced using 4D-Var data assimilation in CY41R2 of the ECMWF IFS, with 137 hybrid sigma/pressure (model) levels in the vertical, with the top level at 0.01 hPa. Atmospheric data are available on these levels and are also interpolated to 37 pressure, 16 potential temperature and one potential vorticity level(s). “Surface or single-level” data are also available, containing two-dimensional parameters such as precipitation, 2-m temperature, top of atmosphere radiation and vertical integrals over the entire atmosphere. The IFS is coupled to a soil model, the parameters of which are also designated as surface parameters, and an ocean wave model. For the current report, ERA5 data were used for the validation of 2-m temperature, precipitation, 10-m wind speed, mean sea level pressure (MSLP), total cloud cover, snowfall, sea surface temperature (SST) and sea ice fraction. Note that, although all ERA5 climate fields

are directly comparable to observations, assimilated fields (e.g. temperature, wind speed and pressure) are expected to be more accurate than non-assimilated fields (e.g. precipitation and snowfall).

2.1.2 CRU Global Gridded Observational Datasets

The CRU high-resolution observational time series dataset is produced by the CRU, University of East Anglia (Harris *et al.*, 2014). The dataset contains monthly time series of precipitation, daily maximum and minimum temperatures, cloud cover and other variables covering all land areas (excluding Antarctica) for 1901–2015. The dataset is gridded to 0.5×0.5 degree resolution, based on analysis of over 4000 individual weather station records. For the current report, CRU time series data (version 4.03) were used for the validation of EC-Earth 2-m temperature and precipitation variables for the periods 1979–2014 (for comparison with ERA5) and 1901–2014.

2.2 Validation Methods and Metrics

The EC-Earth raw data were post-processed (“cmorised”) using international best practices (see Chapter 1) and are archived on a reduced Gaussian grid (512×256 , $N=128$). The CRU and ERA5 datasets were interpolated onto the lower resolution EC-Earth grid using the method of bilinear interpolation and Climate Data Operators (CDO) software. The EC-Earth data were then directly compared with the observational and reanalysis datasets using the bias and mean absolute error (MAE) statistics. The bias statistic is given by:

$$bias_{(i,j)} = \overline{GCM}_{(i,j)} - \overline{OBS}_{(i,j)} \quad (2.1)$$

where the $\overline{GCM}_{(i,j)}$ and $\overline{OBS}_{(i,j)}$ terms represent the GCM and observed/reanalysis values, respectively, at grid point (i,j) , averaged over the time period of interest. To quantify the overall global bias, the mean was calculated over all N grid points using:

$$global_bias = \frac{1}{N} \sum_{i,j} \left(\overline{GCM}_{(i,j)} - \overline{OBS}_{(i,j)} \right) \quad (2.2)$$

The global mean is calculated using weighted averages derived from each grid cell area.

The bias metric allows for the evaluation of the systematic errors of the EC-Earth model but can hide large errors, as positive and negative values can cancel. For this reason, the MAE metric was also used to evaluate the overall global performance of EC-Earth. The MAE statistic is given by:

$$global_MAE = \frac{1}{N} \sum_{i,j} \left| \overline{GCM}_{(i,j)} - \overline{OBS}_{(i,j)} \right| \quad (2.3)$$

The percentage bias and MAE are also considered for precipitation, given by:

$$per_global_bias = \frac{100}{N} \sum_{i,j} \frac{\left(\overline{GCM}_{(i,j)} - \overline{OBS}_{(i,j)} \right)}{\overline{OBS}_{(i,j)}} \quad (2.4)$$

and:

$$per_global_MAE = \frac{100}{N} \sum_{i,j} \frac{\left| \overline{GCM}_{(i,j)} - \overline{OBS}_{(i,j)} \right|}{\overline{OBS}_{(i,j)}} \quad (2.5)$$

The validation presented here considers the following time periods; annual, DJF, MAM (March, April and May), JJA and SON (September, October and November).

2.3 EC-Earth Validation Results

2.3.1 2-m temperature validations

Figure 2.1 presents the spatial distribution of annual mean 2-m temperature for the ERA5 dataset, CRU dataset and each of the five EC-Earth ensemble members for the 36-year period 1979–2014.³ All EC-Earth ensemble members accurately capture the magnitude and spatial characteristics of the historical temperature climate. This is confirmed in Figures 2.2 and 2.3, which present the ERA5 and CRU bias, respectively. The general trend is for EC-Earth to underestimate the temperature over land areas, with some exceptions, such as southern Australia. Over oceans, EC-Earth exhibits a strong warm bias in the Southern Hemisphere. Small differences are noted elsewhere with the exception of the North Atlantic,

which exhibits a cold bias, the magnitude of which varies between ensemble members; the strongest bias is noted for ensemble member r11i1p1f1 (Figure 2.2c).

Validations for DJF are presented in Figures 2.4–2.6 and show a similar signal to the annual results, with a diminished warm bias over the Southern Hemisphere oceans and Antarctica and an enhanced cold bias over most land areas. Conversely, JJA validations exhibit an enhanced warm bias over the southern oceans and Antarctica and a diminished cold bias over land (Figures 2.7–2.9).

The annual and seasonal overall global bias and MAE statistics relative to ERA5 data (1979–2014) for each of the five ensemble members are presented in Table 2.1. The bias statistics are all positive and range from 0.02°C (DJF, r11i1p1f1) to 0.78°C (JJA, r9i1p1f1). The MAE statistics range from 1.21°C (SON, r15i1p1f1) to 2.01°C (MAM, r11i1p1f1). Similarly, the CRU statistics for the period 1901–2014 are presented in Table 2.2. The bias values are all negative (recall that the CRU dataset excludes Antarctica, for which the EC-Earth dataset exhibits a warm bias compared with ERA5, and the oceans), with values ranging from –1.70°C (MAM, r6i1p1f1) to –0.51°C (JJA, r9i1p1f1). The MAE statistics range from 1.55°C (SON, r13i1p1f1) to 2.66°C (DJF, r6i1p1f1). The largest bias and MAE statistics are noted for DJF and MAM; the spatial characteristics of the bias for MAM are similar to those for DJF (Figure 2.6) with the exception that the warm bias over North-East Asia is not evident.

The ERA5 and EC-Earth mean global annual 2-m temperature time series (1979–2014), presented in Figure 2.10a, demonstrate a consistent overestimation of EC-Earth temperatures. Figure 2.10b, the annual anomalies with respect to the 1981–2010 mean, shows good agreement between ERA5 reanalysis data and EC-Earth ensemble members. However, the EC-Earth temperature rise is overestimated for the later years. The CRU and EC-Earth mean global annual 2-m temperature time series (1901–2014), presented in Figure 2.11a, demonstrate a consistent underestimation of EC-Earth land surface temperatures. The temperature anomalies for the period 1901–2014 (Figure 2.11b) again show a slight overestimation of temperature rise for the later years.

³ Note that the 1979–2014 period was chosen as it is the longest common time period of the ERA5, CRU and EC-Earth datasets. CRU datasets cover the period 1901–2014; analyses over this time period are considered in subsequent validations.

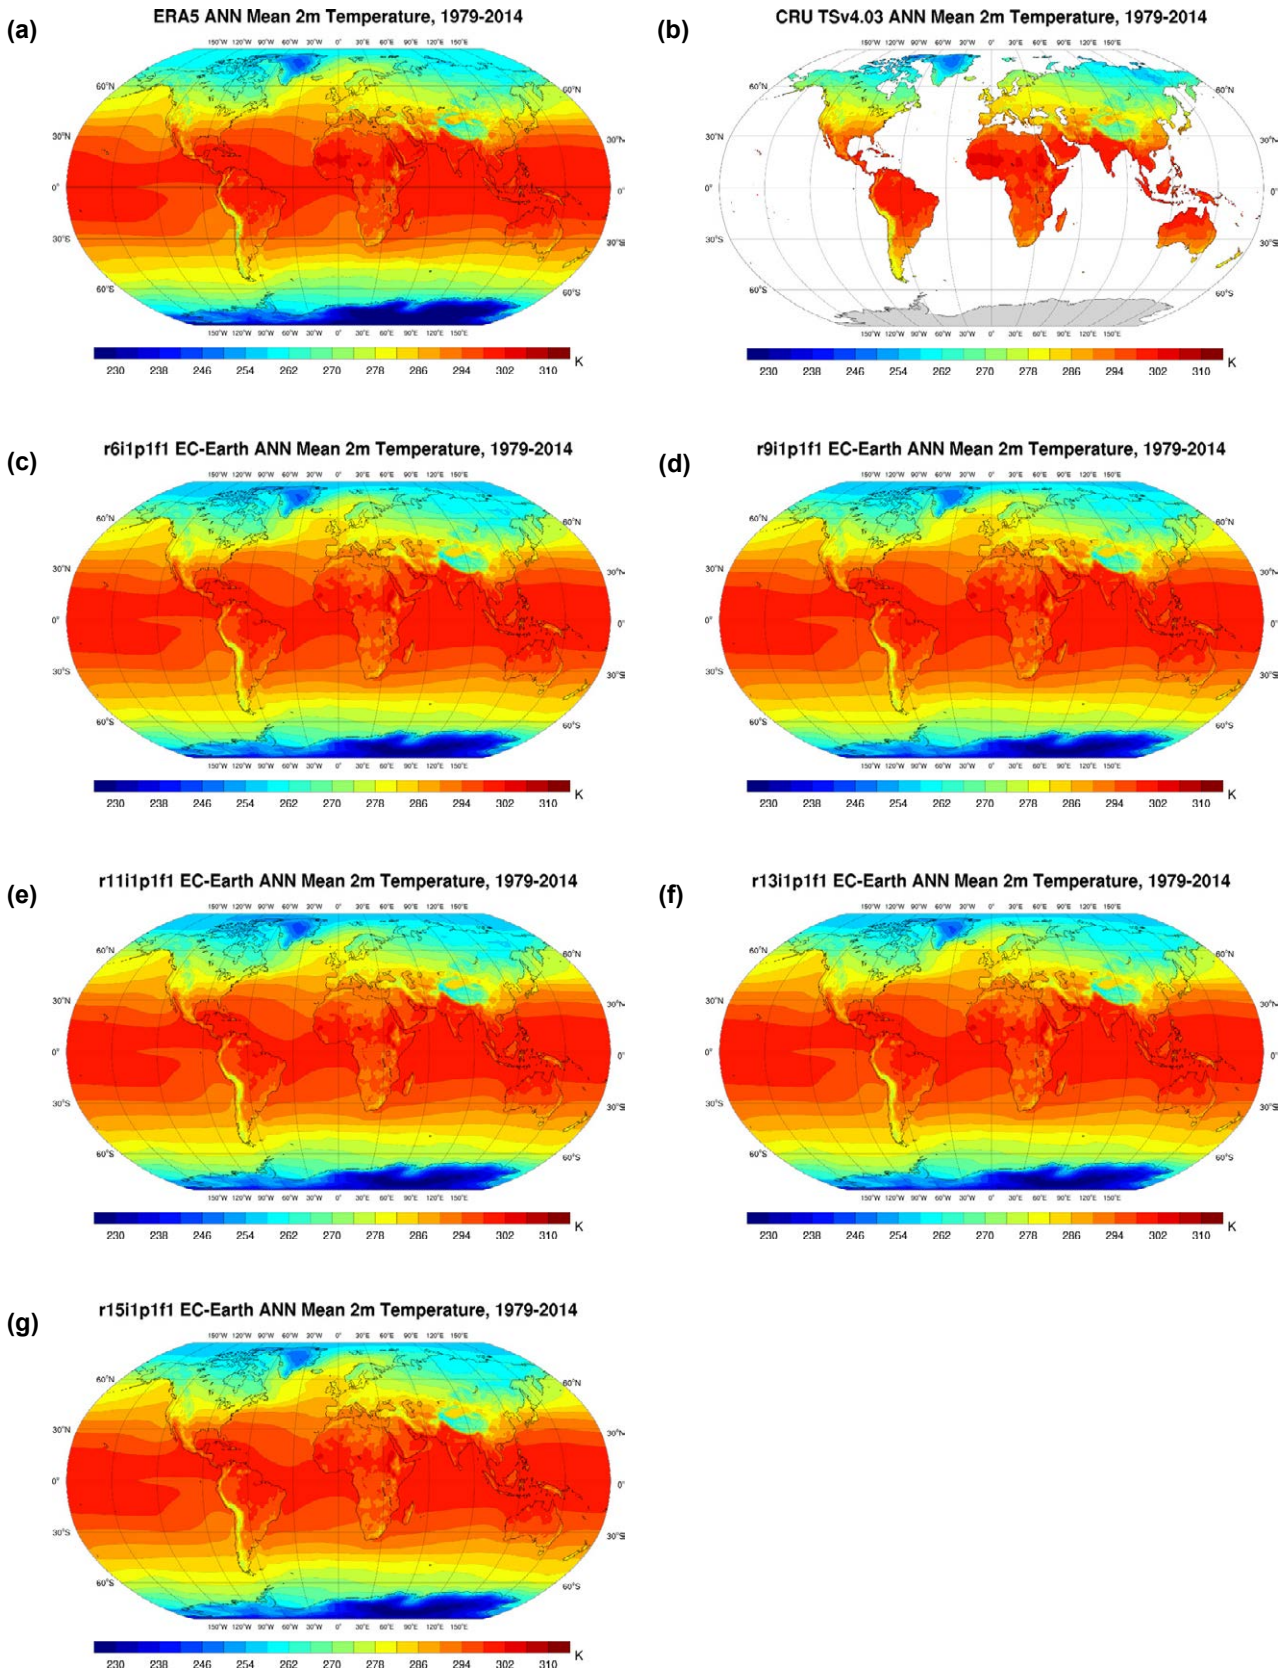

Figure 2.1. Annual mean 2-m temperature, 1979–2014: (a) ERA5 reanalysis, (b) CRU_ts4.03 observations, (c) EC-Earth r6i1p1f1, (d) EC-Earth r9i1p1f1, (e) EC-Earth r11i1p1f1, (f) EC-Earth r13i1p1f1 and (g) EC-Earth r15i1p1f1.

Figure 2.9. EC-Earth 2-m temperature bias for JJA, 1979–2014 (EC-Earth minus CRU_{ts4.03}): (a) EC-Earth r6i1p1f1, (b) EC-Earth r9i1p1f1, (c) EC-Earth r11i1p1f1, (d) EC-Earth r13i1p1f1 and (e) EC-Earth r15i1p1f1.

Table 2.1. Mean global annual and seasonal 2-m temperature bias and MAE (°C) for each of the five EC-Earth ensemble members^a

Time period	r6i1p1f1		r9i1p1f1		r11i1p1f1		r13i1p1f1		r15i1p1f1	
	Bias	MAE	Bias	MAE	Bias	MAE	Bias	MAE	Bias	MAE
Annual	0.33	1.42	0.67	1.38	0.18	1.59	0.49	1.40	0.54	1.35
DJF	0.21	1.60	0.62	1.56	0.02	1.80	0.39	1.58	0.45	1.51
MAM	0.31	1.83	0.61	1.79	0.15	2.01	0.44	1.82	0.48	1.76
JJA	0.49	1.42	0.78	1.43	0.37	1.54	0.63	1.43	0.66	1.39
SON	0.33	1.24	0.67	1.23	0.17	1.39	0.51	1.23	0.55	1.21

^aIn each case the model data are compared with ERA5 reanalysis data for the period 1979–2014.

Table 2.2. Mean global annual and seasonal 2-m temperature bias and MAE (°C) for each of the five EC-Earth ensemble members^a

Time period	r6i1p1f1		r9i1p1f1		r11i1p1f1		r13i1p1f1		r15i1p1f1	
	Bias	MAE	Bias	MAE	Bias	MAE	Bias	MAE	Bias	MAE
Annual	-1.32	1.81	-0.89	1.60	-1.11	1.71	-0.91	1.60	-0.97	1.63
DJF	-1.62	2.66	-1.07	2.48	-1.37	2.55	-1.12	2.46	-1.17	2.47
MAM	-1.70	2.36	-1.29	2.14	-1.48	2.25	-1.30	2.14	-1.38	2.18
JJA	-0.83	1.74	-0.51	1.60	-0.66	1.66	-0.54	1.61	-0.58	1.61
SON	-1.12	1.78	-0.69	1.57	-0.91	1.67	-0.66	1.55	-0.77	1.60

^aIn each case the model data are compared with CRU_ts4.03 observational data for the period 1901–2014. The temperature data are confined to land points and exclude Antarctica.

Figure 2.10. Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: (a) 2-m temperature and (b) 2-m temperature anomalies with respect to the 30-year period 1981–2010.

Figure 2.11. Comparison of EC-Earth ensemble members with CRU_ts4.03 observations for the period 1901–2014: (a) 2-m land temperature and (b) 2-m land temperature anomalies with respect to the 30-year period 1981–2010. The temperature data are confined to land points and exclude Antarctica.

2.3.2 Precipitation validations

Figure 2.12 presents the spatial distribution of annual precipitation (mm/day) for the ERA5 dataset, the CRU dataset and each of the five EC-Earth ensemble members for the 36-year period 1979–2014. All EC-Earth ensemble members accurately capture the magnitude and spatial characteristics of the historical precipitation climate. This is confirmed in Figures 2.13 and 2.14, showing the ERA5 and CRU bias, respectively. The largest differences are noted around the Intertropical Convergence Zone (ITCZ), in particular over the ITCZ ocean regions, the north-east region of South America (dry bias), the remaining regions of South America (small wet bias) and south/central Africa (small wet bias). Validations for DJF and JJA are presented in Figures 2.15–2.20 and show a similar signal to the annual results, with enhanced biases noted over the ICTZ regions. The wet/dry bands around the ICTZ (e.g. Figures 2.13, 2.16 and 2.19) suggest that the precipitation biases result from a slight incorrect positioning of the ICTZ as opposed to an error in the magnitude of precipitation amounts. All EC-Earth ensemble members are similar, with small variations between members.

The annual and seasonal overall global bias and MAE statistics relative to ERA5 data (1979–2014) for each of the five ensemble members are presented in Table 2.3. The bias statistics range from -0.055 mm/day (JJA, r11i1p1f1) to 0.061 mm/day (DJF, r15i1p1f1). The MAE statistics range from 0.537 mm/day (annual, r15i1p1f1) to 0.879 mm/day (MAM, r11i1p1f1). The percentage bias and MAE statistics are presented in Table 2.4. The percentage bias statistics range from 2.5% (SON, r11i1p1f1) to 16.4% (MAM, r9i1p1f1 and r11i1p1f1). The percentage MAE statistics range from 26.2% (SON, r15i1p1f1) to 44.3% (MAM, r11i1p1f1). Similarly, the CRU statistics for the period 1901–2014 are presented in Table 2.5. The bias values range from -0.006 mm/day (JJA, r13i1p1f1) to 0.26 mm/day (DJF, r9i1p1f1). The MAE statistics range from 0.662 mm/day (annual, r13i1p1f1) to 0.858 mm/day (JJA, r11i1p1f1 and r15i1p1f1). The percentage bias and MAE statistics are not presented for CRU data as these datasets are made available with units of mm/month with a precision of one decimal place. This rounding results in zero values over many dry areas; hence, a quotient cannot be calculated.

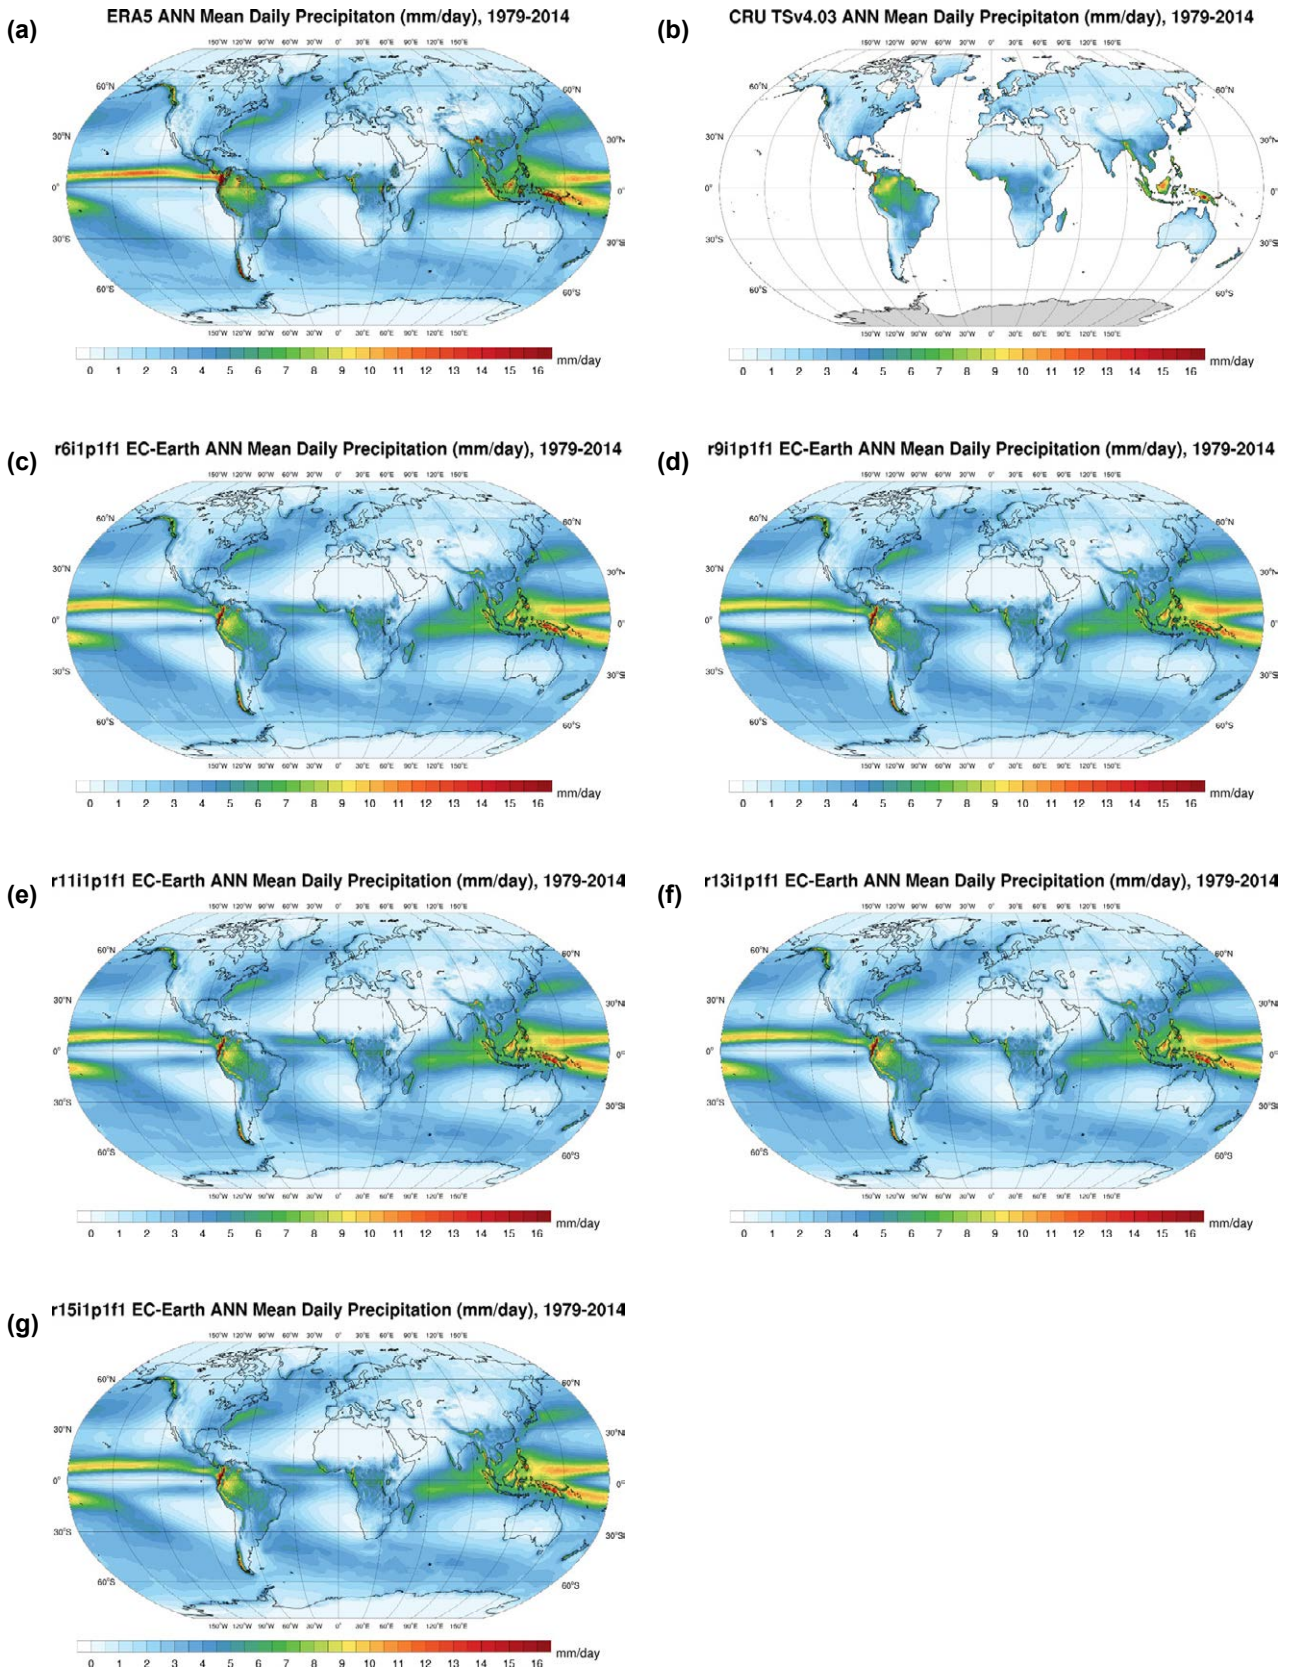

Figure 2.12. Annual mean daily precipitation (mm/day), 1979–2014: (a) ERA5 reanalysis, (b) CRU_ts4.03 observations, (c) EC-Earth r6i1p1f1, (d) EC-Earth r9i1p1f1, (e) EC-Earth r11i1p1f1, (f) EC-Earth r13i1p1f1 and (g) EC-Earth r15i1p1f1.

^aIn each case the model data are compared with CRU_ts4.03 observational data for the period 1901–2014. The data are confined to land points and exclude Antarctica.

The ERA5 and EC-Earth mean global annual precipitation time series (1979–2014), presented in Figure 2.21a, demonstrate good agreement except for the period 1989–1996, when all EC-Earth ensemble members overestimate precipitation. In particular, the dry period around 1992 is not accurately resolved by EC-Earth. Figure 2.21b, the annual anomalies with respect to the 1981–2010 mean, shows good agreement between ERA5 and EC-Earth, with a clear rise in global precipitation evident from the early 1990s. The CRU and EC-Earth mean global annual precipitation time series (1901–2014), presented in Figure 2.22a, demonstrate a consistent overestimation of EC-Earth precipitation over land during 1850–1945 and 1985–2014. The precipitation anomalies for the period 1901–2014 (Figure 2.22b) all show a clear increase in precipitation over land from around 1995.

2.3.3 10-m wind speed validations

Figures 2.23–2.28 compare the EC-Earth 10-m wind speed (m/s) data with ERA5 data for the period 1979–2014. The figures demonstrate that all EC-Earth ensemble members accurately capture

the magnitude and spatial characteristics of the historical 10-m wind speed climate for the annual, DJF and JJA time periods. The general trend is for EC-Earth to slightly overestimate wind speeds over land and underestimate wind speeds in the equatorial ocean regions.

The annual and seasonal overall global bias and MAE statistics relative to ERA5 data (1979–2014) for each of the five ensemble members are presented in Table 2.6. The bias statistics are all positive, ranging from 0.01 m/s (JJA, r6i1p1f1) to 0.158 m/s (DJF, r6i1p1f1). The MAE statistics range from 0.393 m/s (annual, r15i1p1f1) to 0.537 m/s (DJF, r11i1p1f1).

The ERA5 and EC-Earth mean global annual 10-m wind speed time series (1979–2014), presented in Figure 2.29a, demonstrate good agreement. However, all EC-Earth ensemble members exhibit a slight overestimation of ~0.1 m/s during the period 1979–1997. Figure 2.29b shows the annual anomalies with respect to the 1981–2010 mean; all ERA5 and EC-Earth annual values are within the range of ±0.1 m/s.

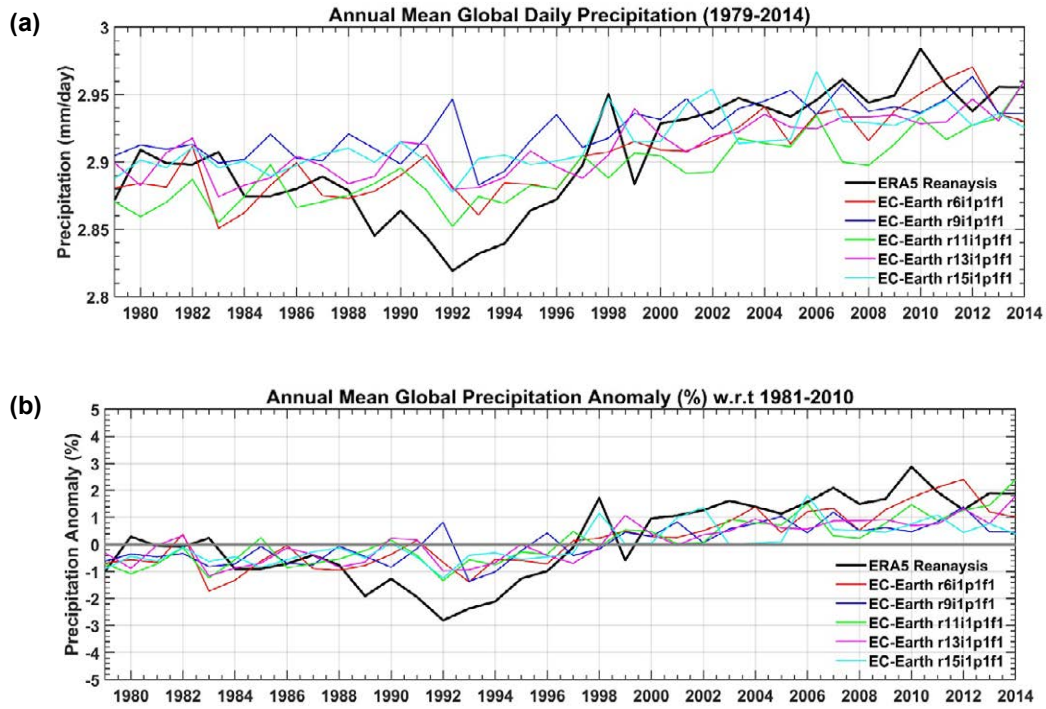

Figure 2.21. Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: (a) precipitation and (b) precipitation anomalies (%) with respect to the 30-year period 1981–2010.

Figure 2.22. Comparison of EC-Earth ensemble members with CRU_ts4.03 observational data for the period 1901–2014: (a) land precipitation and (b) land precipitation anomalies (%) with respect to the 30-year period 1981–2010. A 5-year running mean was applied to all datasets. The temperature data are confined to land points and exclude Antarctica.

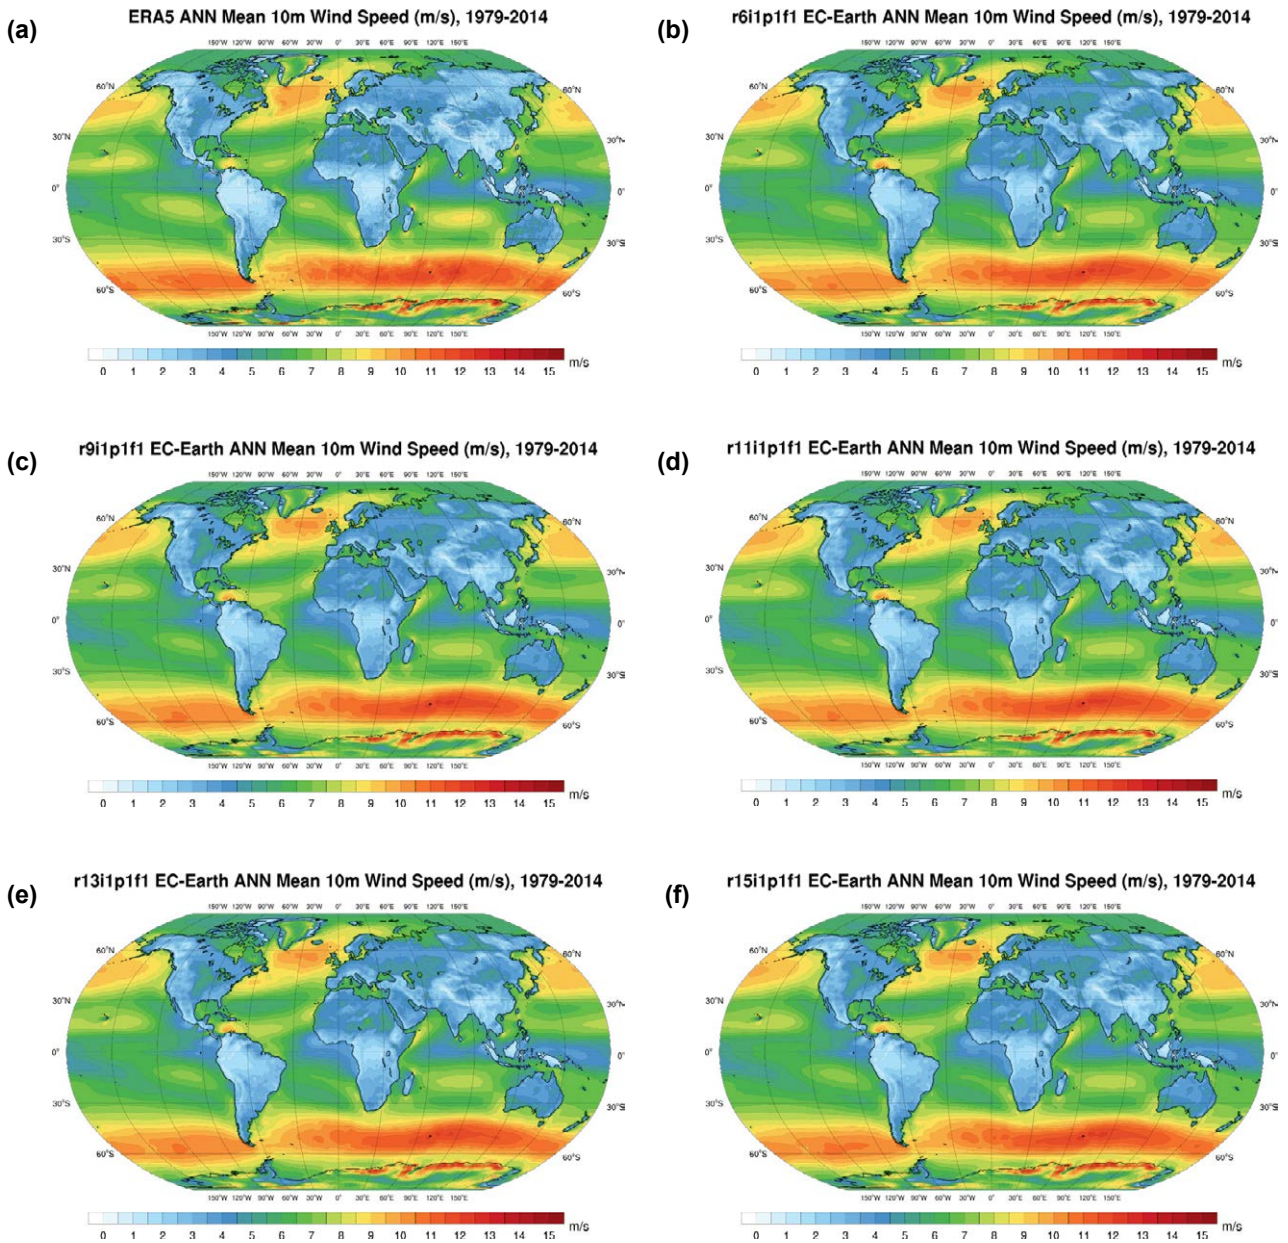

Figure 2.23. Annual mean 10-m wind speed (m/s), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1.

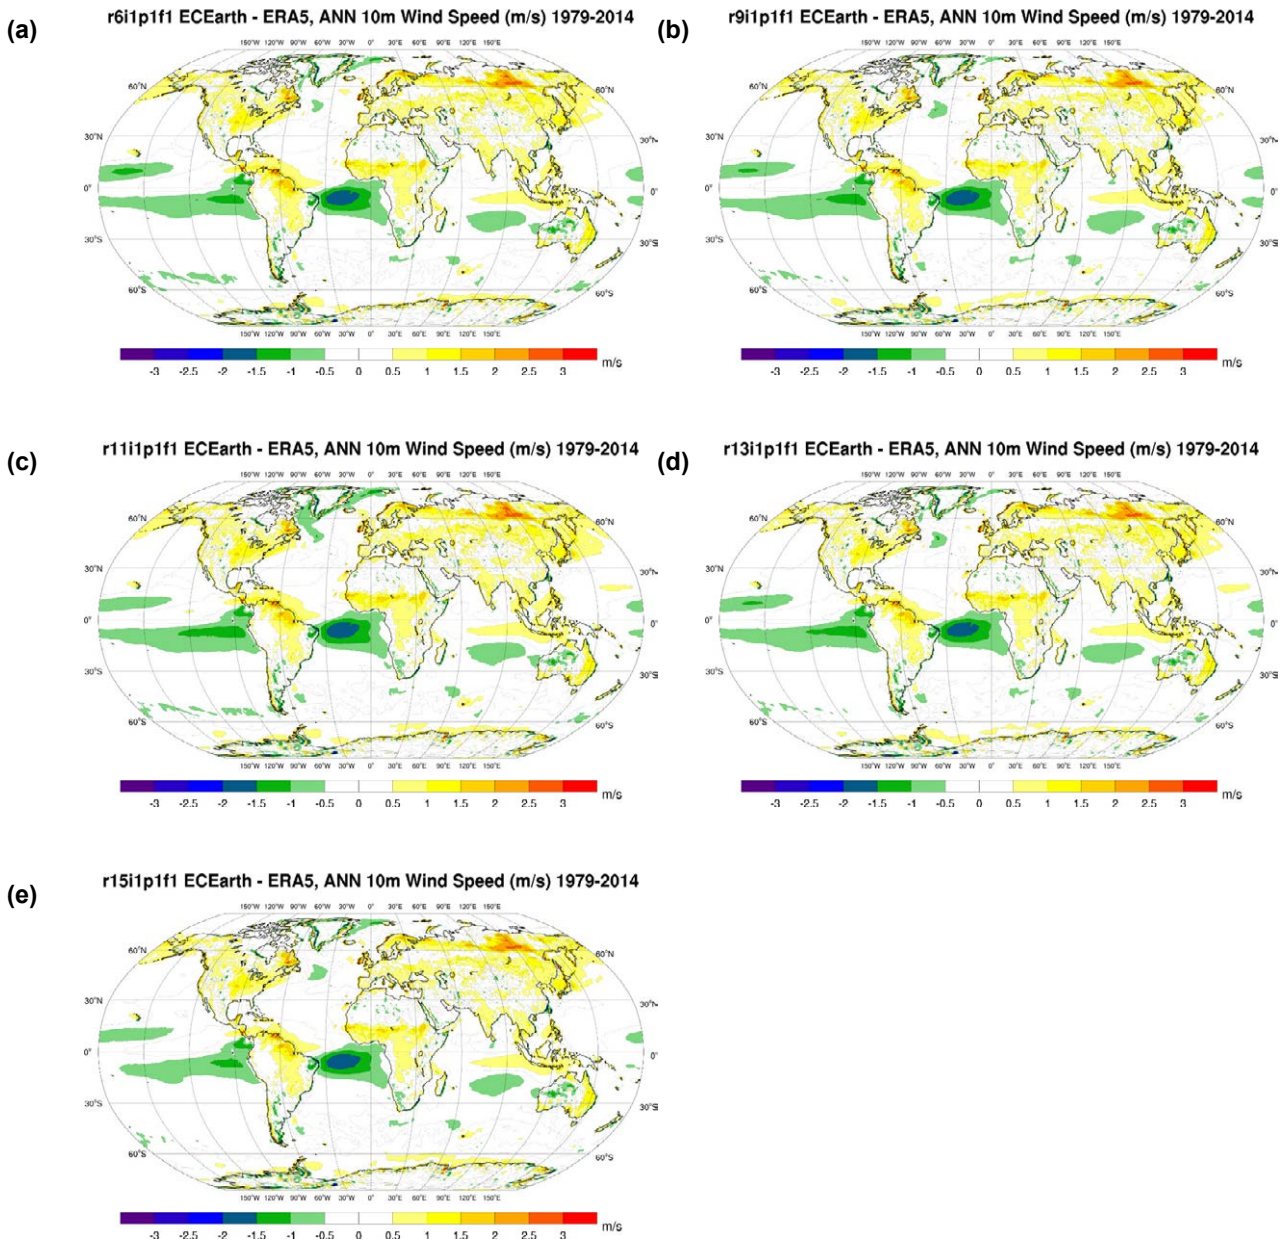

Figure 2.24. EC-Earth annual 10-m wind speed bias (m/s), 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1f1, (b) EC-Earth r9i1p1f1, (c) EC-Earth r11i1p1f1, (d) EC-Earth r13i1p1f1 and (e) EC-Earth r15i1p1f1.

^aIn each case the model data are compared with ERA5 reanalysis data for the period 1979–2014.

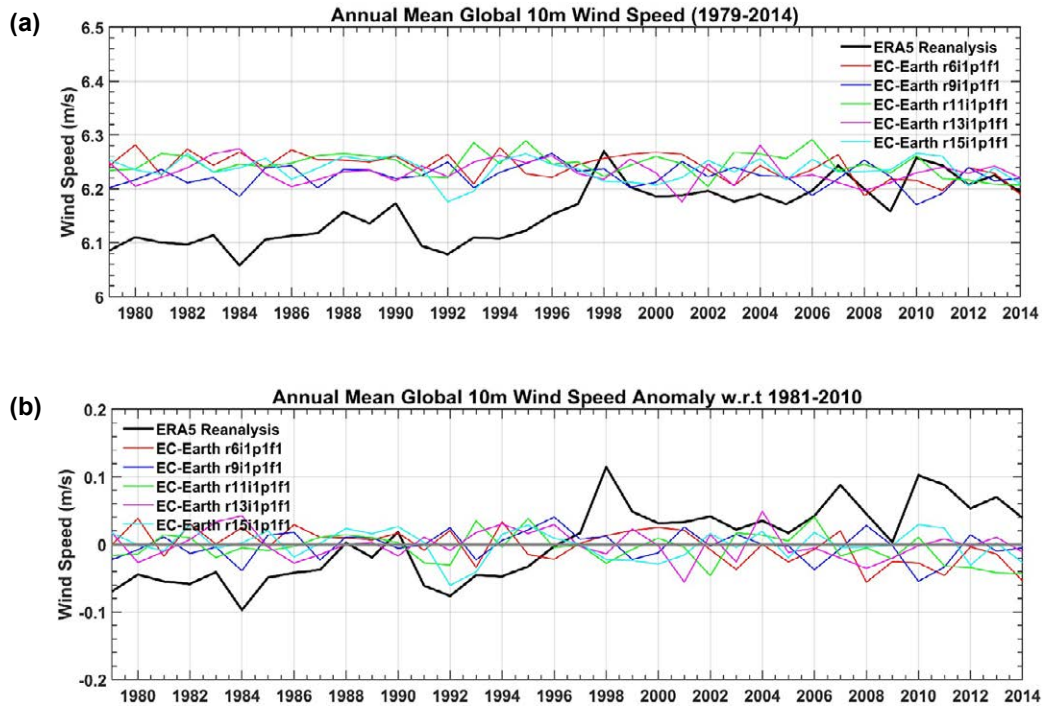

Figure 2.29. Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: (a) 10-m wind speed and (b) 10-m wind speed anomalies with respect to the 30-year period 1981–2010.

2.3.4 Mean sea level pressure validations

Figure 2.30 presents the spatial distribution of mean annual MSLP for ERA5 and each of the five EC-Earth ensemble members for the 36-year period 1979–2014. All EC-Earth ensemble members accurately capture the magnitude and spatial characteristics of the historical MSLP climate. Figure 2.31 demonstrates that the differences relative to ERA5 data are similar for all EC-Earth ensemble members – an underestimate over the southern subtropical and North Pacific regions. All other regions exhibit a small positive bias (or small differences). MSLP validations for DJF (Figures 2.32 and 2.33) follow a similar (but enhanced) trend as the annual biases. In addition, a negative bias is evident over the UK and Ireland. MSLP validations for JJA (Figures 2.34 and 2.35) show a negative bias over north-east Europe and the southern subtropical regions, and a positive bias over the poles and the UK

and Ireland, the magnitude of which varies between ensemble members; the strongest bias is noted for ensemble member r11i1p1f1 (Figure 2.35c).

The annual and seasonal overall global bias and MAE statistics relative to ERA5 data (1979–2014) for each of the five ensemble members are presented in Table 2.7. The bias statistics are all negative, ranging from -0.16 hPa (JJA, r11i1p1f1) to -0.05 hPa (DJF, r11i1p1f1). The MAE statistics range from 0.68 hPa (annual, r15i1p1f1) to 1.29 hPa (DJF, r11i1p1f1).

The ERA5 and EC-Earth mean global annual MSLP time series (1979–2014), presented in Figure 2.36a, demonstrate good agreement. However, all EC-Earth ensemble members exhibit a slight underestimation of MSLP of ~ 0.2 hPa from about 1990. Figure 2.36b shows the annual anomalies with respect to the 1981–2010 mean; all ERA5 and EC-Earth annual values are within the range of -0.2 hPa to 0.1 hPa.

Figure 2.30. Mean annual MSLP (hPa), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1.

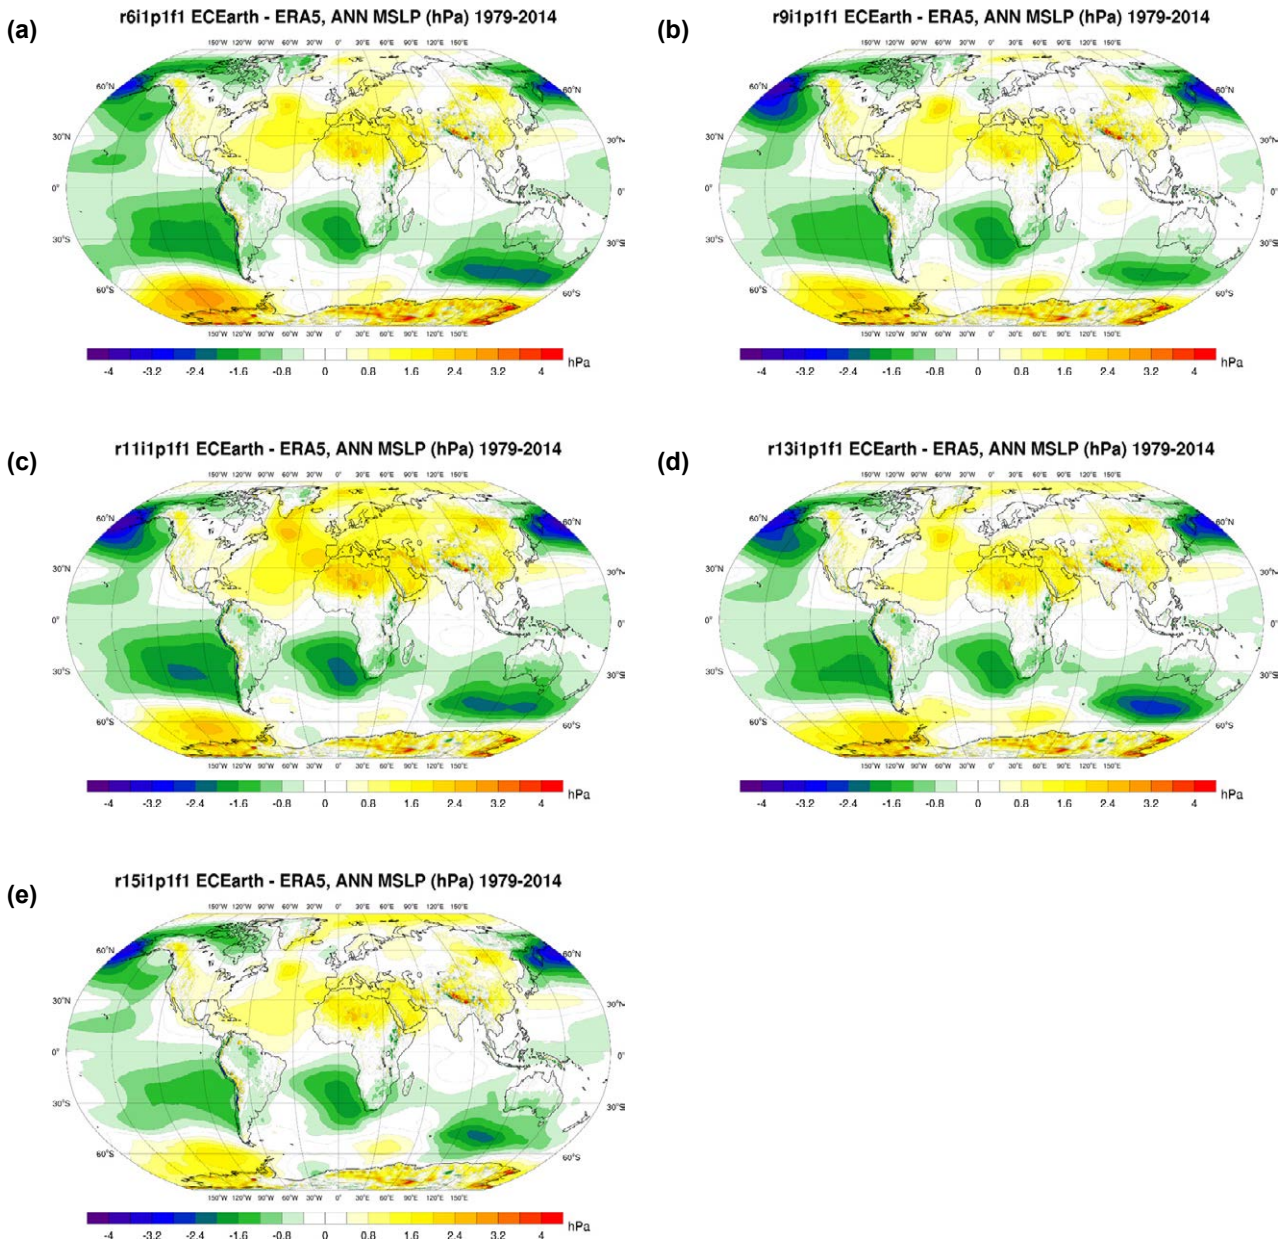

Figure 2.31. EC-Earth mean annual MSLP bias (hPa), 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1f1, (b) EC-Earth r9i1p1f1, (c) EC-Earth r11i1p1f1, (d) EC-Earth r13i1p1f1 and (e) EC-Earth r15i1p1f1.

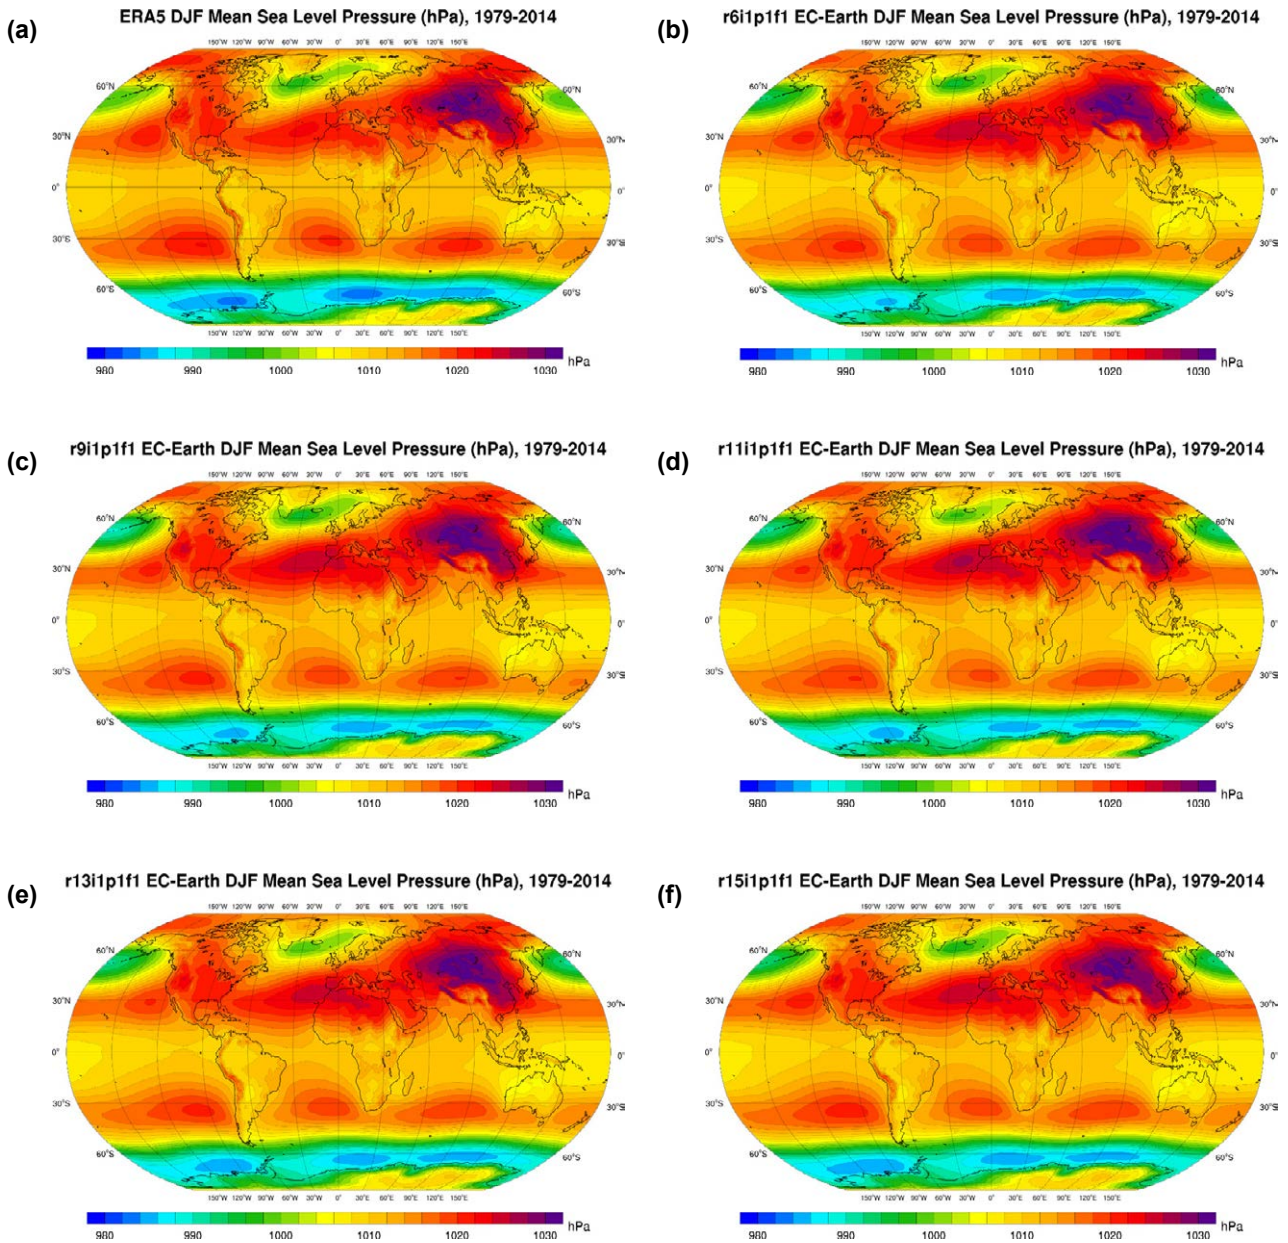

Figure 2.32. MSLP (hPa) for DJF, 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1.

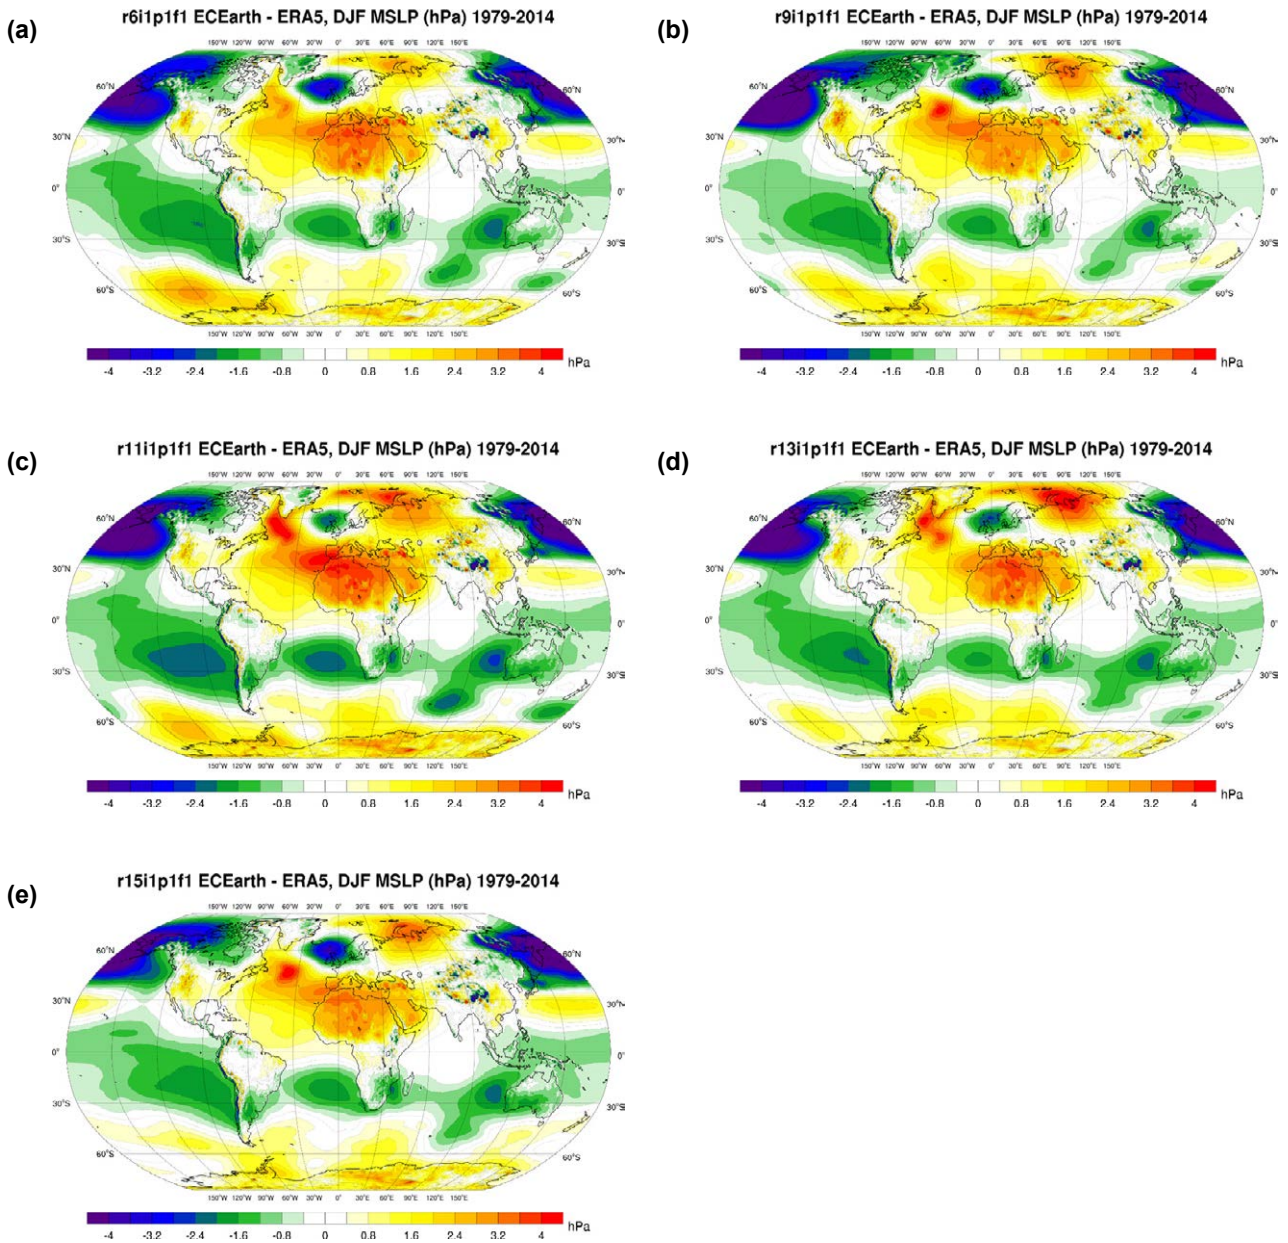

Figure 2.33. EC-Earth MSLP bias (hPa) for DJF, 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1f1, (b) EC-Earth r9i1p1f1, (c) EC-Earth r11i1p1f1, (d) EC-Earth r13i1p1f1 and (e) EC-Earth r15i1p1f1.

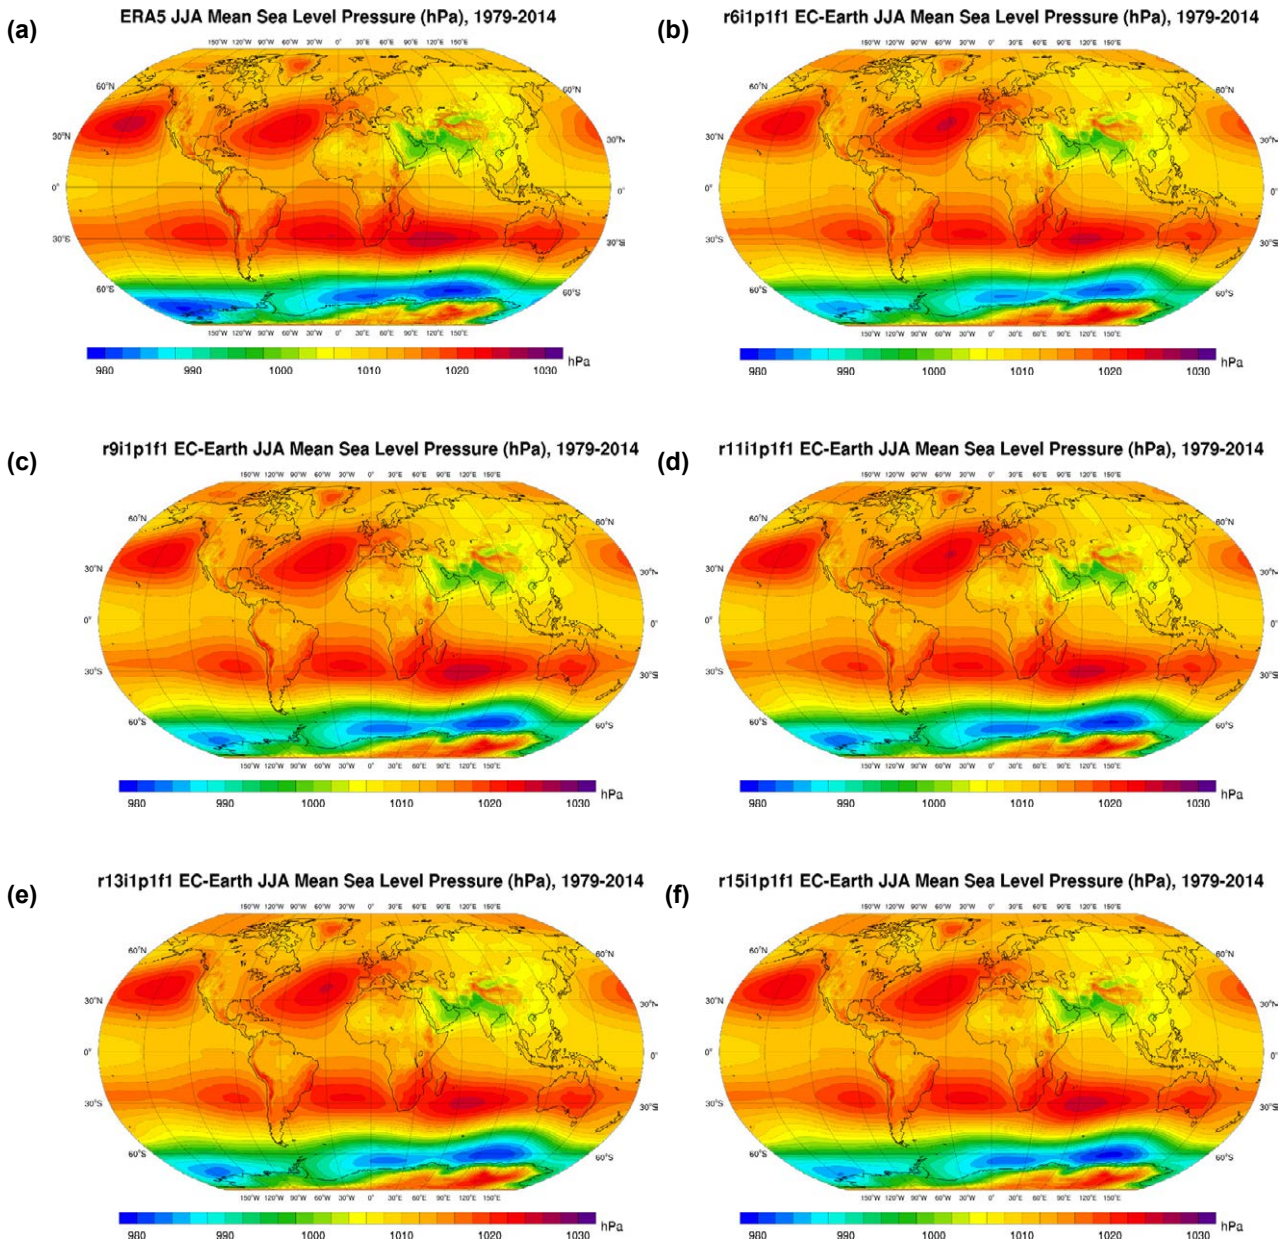

Figure 2.34. MSLP for JJA (hPa), 1979–2014: (a) ERA5 reanalysis, (b) EC-Earth r6i1p1f1, (c) EC-Earth r9i1p1f1, (d) EC-Earth r11i1p1f1, (e) EC-Earth r13i1p1f1 and (f) EC-Earth r15i1p1f1.

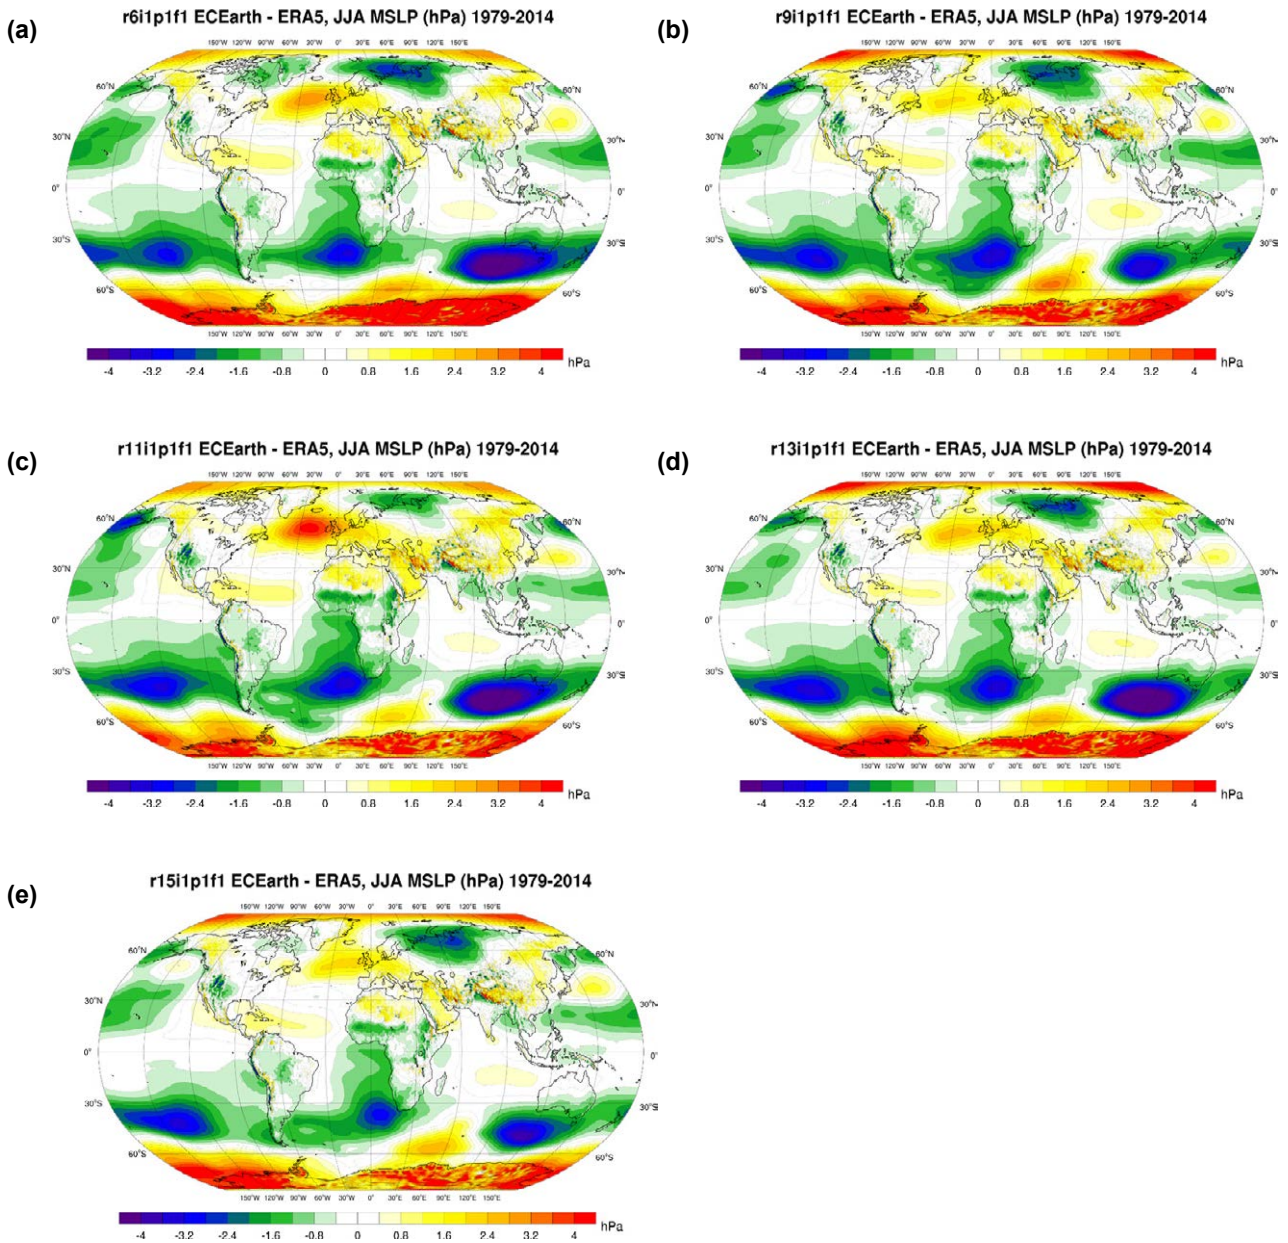

Figure 2.35. EC-Earth MSLP bias (hPa) for JJA, 1979–2014 (ERA5 reanalysis minus EC-Earth): (a) EC-Earth r6i1p1f1, (b) EC-Earth r9i1p1f1, (c) EC-Earth r11i1p1f1, (d) EC-Earth r13i1p1f1 and (e) EC-Earth r15i1p1f1.

^aIn each case the model data are compared with ERA5 reanalysis data for the period 1979–2014.

Figure 2.36. Comparison of EC-Earth ensemble members with ERA5 reanalysis data for the period 1979–2014: (a) MSLP and (b) MSLP anomalies with respect to the 30-year period 1981–2010.

2.3.5 Total cloud cover validations

Figure 2.37, which shows the ERA5 and EC-Earth spatial distribution of annual mean total cloud cover, demonstrates that all EC-Earth ensemble members accurately capture the magnitude and spatial characteristics of the historical cloud climate. Figure 2.38 demonstrates that the differences relative to ERA5 data are similar for all EC-Earth ensemble members – an underestimate over the Arctic, Central America, Central Africa and the southern subtropical ocean regions. All other regions exhibit a slight positive

bias (or small differences). Cloud cover validations for DJF (Figures 2.39 and 2.40) follow a similar (but enhanced) trend as the annual validations. In addition, negative (positive) biases are noted over the Middle East and India (Australia, South Africa, Indian Ocean and western Pacific) regions during DJF. Total cloud validations for JJA (Figures 2.41 and 2.42) show a positive bias over North America, Russia and the northern subtropical and equatorial ocean regions, and a negative bias over the southern subtropical regions, the Indian Ocean, the north-east Pacific Ocean and India.
